

# Package ‘RJDemetra’

June 26, 2019

**Type** Package

**Title** Interface to 'JDemetra+' Seasonal Adjustment Software

**Version** 0.1.3

**Description** Interface around 'JDemetra+' (<<https://github.com/jdemetra/jdemetra-app>>), the seasonal adjustment software officially recommended to the members of the European Statistical System (ESS) and the European System of Central Banks.  
It offers full access to all options and outputs of 'JDemetra+', including the two leading seasonal adjustment methods TRAMO/SEATS+ and X-12ARIMA/X-13ARIMA-SEATS.

**Depends** R (>= 3.1.1),

**Imports** rJava (>= 0.9-8), graphics, grDevices, methods, stats, utils

**SystemRequirements** Java SE 8 or higher

**License** EUPL

**URL** <https://github.com/jdemetra/rjdemetra>

**LazyData** TRUE

**Suggests** knitr, rmarkdown

**RoxygenNote** 6.1.1

**BugReports** <https://github.com/jdemetra/rjdemetra/issues>

**Encoding** UTF-8

**NeedsCompilation** no

**Author** Alain Quartier-la-Tente [aut, cre],  
Anna Michalek [aut],  
Jean Palate [aut],  
Raf Baeyens [aut]

**Maintainer** Alain Quartier-la-Tente <[alain.quartier@yahoo.fr](mailto:alain.quartier@yahoo.fr)>

**Repository** CRAN

**Date/Publication** 2019-06-26 10:30:17 UTC

--------------	-----------

---

add_sa_item	<i>Add a seasonnaly adjust model to a multi-processing</i>
-------------	--

---

### Description

Function to add a new seasonnaly adjust object (class c("SA", "X13") or c("SA", "TRAMO\_SEATS") in a workspace object.

### Usage

```
add_sa_item(workspace, multiprocessing, sa_obj, name)
```

### Arguments

workspace	the workspace to add the seasonnaly adjust model.
multiprocessing	the name or index of the multiprocessing to add the seasonnaly adjust model.
sa_obj	the seasonnaly adjust object to export.
name	The name of the seasonnaly adjust model in the multiprocessing. By default the name of the sa_obj is used.

**See Also**

[load\\_workspace](#), [save\\_workspace](#)

**Examples**

```
dir <- tempdir()
spec_x13 <- x13_spec(spec = "RSA5c", easter.enabled = FALSE)
sa_x13 <- x13(ipi_c_eu[, "FR"], spec = spec_x13)
spec_ts <- tramoseats_spec(spec = "RSA5")
sa_ts <- tramoseats(ipi_c_eu[, "FR"], spec = spec_ts)

wk <- new_workspace()
new_multiprocessing(wk, "sa1")
add_sa_item(wk, "sa1", sa_x13, "X13")
add_sa_item(wk, "sa1", sa_ts, "TramoSeats")

save_workspace(wk, file.path(dir, "workspace.xml"))
```

---

compute

*Compute the multi-processing from a workspace*

---

**Description**

Function to compute all the multi-processings or a given one from a workspace. By default the workspace only contains definitions: computation is needed to get the seasonal adjustment model (with [get\\_model](#)).

**Usage**

```
compute(workspace, i)
```

**Arguments**

workspace	the workspace to compute.
i	a character or numeric indicating the name or the index of the multiprocessing to compute. By default all the multi-processings are compute.

**See Also**

[get\\_model](#)

## Examples

```
spec_x13 <- x13_spec(spec = "RSA5c", easter.enabled = FALSE)
sa_x13 <- x13(ipi_c_eu[, "FR"], spec = spec_x13)

wk <- new_workspace()
mp <- new_multiprocessing(wk, "sa1")
add_sa_item(wk, "sa1", sa_x13, "X13")
sa_item1 <- get_object(mp, 1)

get_model(sa_item1, wk) # Returns NULL

compute(wk)

get_model(sa_item1, wk) # Returns the SA model sa_x13
```

---

count

*Count the number of objects inside a workspace or multiprocessing*

---

## Description

Generics functions to count the number of multiprocessing (respectively sa\_item) inside a workspace (respectively multiprocessing).

## Usage

```
count(x)
```

## Arguments

x                   the workspace or the codemultiprocessing.

## See Also

Other functions to get informations from a workspace, multiprocessing or sa\_item: [get\\_model](#), [get\\_name](#), [get\\_ts](#).

## Examples

```
wk <- new_workspace()
mp <- new_multiprocessing(wk, "sa1")
count(wk) # 1 multiprocessing inside the workspace wk
count(mp) # 0 sa_item inside the multiprocessing mp
```

---

get_model	<i>Get the seasonally adjusted model from a workspace</i>
-----------	---

---

### Description

Generics functions to get seasonally adjusted model(s) from workspace, multiprocessing or sa\_item object. get\_model returns a "SA" objects while get\_jmodel returns the Java objects of the models.

### Usage

```
get_jmodel(x, workspace, userdefined = NULL, progress_bar = TRUE)
```

```
get_model(x, workspace, userdefined = NULL, progress_bar = TRUE)
```

### Arguments

x	the object to get the seasonally adjusted model.
workspace	the workspace object where models are stored. If x is a workspace object this parameter is not used.
userdefined	vector with characters for additional output variables. (see <a href="#">x13</a> or <a href="#">tramoseats</a> ).
progress_bar	boolean: if TRUE a progress bar is printed.

### Value

get\_model() returns a seasonnaly adjust object (class c("SA", "X13") or c("SA", "TRAMO\_SEATS") or list of seasonnaly adjust objects:

- if x is a sa\_item object, get\_model(x) returns a "SA" object (or a [jSA](#) object with get\_jmodel(x));
- if x is a multiprocessing object, get\_ts(x) returns list of length the number of sa\_items, each element containing a "SA" object (or a [jSA](#) object with get\_jmodel(x));
- if x is a workspace object, get\_ts(x) returns list of length the number of multiprocessing, each element containing a list of a "SA" object (or a [jSA](#) object with get\_jmodel(x)).

### See Also

Other functions to get informations from a workspace, multiprocessing or sa\_item: [count](#), [get\\_name](#), [get\\_ts](#).

[compute](#)

## Examples

```
spec_x13 <- x13_spec(spec = "RSA5c", easter.enabled = FALSE)
sa_x13 <- x13(ipi_c_eu[, "FR"], spec = spec_x13)
spec_ts <- tramoseats_spec(spec = "RSA5")
sa_ts <- tramoseats(ipi_c_eu[, "FR"], spec = spec_ts)

wk <- new_workspace()
mp <- new_multiprocessing(wk, "sa1")
add_sa_item(wk, "sa1", sa_x13, "X13")
add_sa_item(wk, "sa1", sa_ts, "TramoSeats")

compute(wk) # It's important to compute the workspace to get the SA model
sa_item1 <- get_object(mp, 1)

get_model(sa_item1, wk) # Extract the model of the sa_item1: its the object sa_x13

# To get all the models of the multiprocessing mp:
get_model(mp, wk)

# To get all the models of the workspace wk:
get_model(wk)
```

---

get\_name

*Get the Java name of a multiprocessing or a sa\_item*

---

## Description

Generics functions to get the Java name of a multiprocessing or a sa\_item.

## Usage

```
get_name(x)
```

## Arguments

x                    the object to get the name from.

## Value

A character.

## See Also

Other functions to get informations from a workspace, multiprocessing or sa\_item: [count](#), [get\\_model](#), [get\\_ts](#).

**Examples**

```

spec_x13 <- x13_spec(spec = "RSA5c", easter.enabled = FALSE)
sa_x13 <- x13(ipi_c_eu[, "FR"], spec = spec_x13)
spec_ts <- tramoseats_spec(spec = "RSA5")
sa_ts <- tramoseats(ipi_c_eu[, "FR"], spec = spec_ts)

wk <- new_workspace()
mp <- new_multiprocessing(wk, "sa1")
add_sa_item(wk, "sa1", sa_x13, "X13")
add_sa_item(wk, "sa1", sa_ts, "TramoSeats")

sa_item1 <- get_object(mp, 1)
sa_item2 <- get_object(mp, 2)

get_name(sa_item1) # returns "X13"
get_name(sa_item2) # returns "TramoSeats"

get_name(mp) # returns "sa1"

# To get all the name of the sa_items inside a multiprocessing:
sapply(get_all_objects(mp), get_name)

# To get all the name of the multiprocessings inside a workspace:
sapply(get_all_objects(wk), get_name)

# To get all the name of the sa_items inside a workspace:
lapply(get_all_objects(wk), function(mp){
  sapply(get_all_objects(mp), get_name)
})

```

---

get\_object

*Get objects inside a workspace or multiprocessing*

---

**Description**

Generics functions to get all (`get_all_objects()`) multiprocessing (respectively `sa_item`) from a workspace (respectively multiprocessing) or to get a given one (`get_object()`).

**Usage**

```
get_object(x, pos = 1)
```

```
get_all_objects(x)
```

**Arguments**

`x` the object where to extract the multiprocessing or the `sa_item`.  
`pos` the index of the object to extract.

**Value**

An object of class `multiprocessing` or `sa_item` (for `get_object()`) or a list of objects of class `multiprocessing` or `sa_item` (for `get_all_objects()`).

**See Also**

Other functions to get informations from a workspace, `multiprocessing` or `sa_item`: [count](#), [get\\_model](#), [get\\_name](#), [get\\_ts](#).

**Examples**

```
sa_x13 <- x13(ipi_c_eu[, "FR"], spec = "RSA5c")

wk <- new_workspace()
mp <- new_multiprocessing(wk, "sa1")
add_sa_item(wk, "sa1", sa_x13, "X13")

# Other way to get the multiprocessing:
mp <- get_object(wk, 1)
# To get the sa_item object:
sa_item <- get_object(mp, 1)
```

---

get\_ts

*Get the input raw time series*

---

**Description**

Generics functions to get the input raw time series of a workspace, `multiprocessing`, `sa_item` or SA object.

**Usage**

```
get_ts(x)
```

**Arguments**

`x` the object where to get the time series.

**Value**

`get_ts()` returns a `ts` object or list of `ts` objects:

- if `x` is a `sa_item` or a SA object, `get_ts(x)` returns a single `ts` object;
- if `x` is a `multiprocessing` object, `get_ts(x)` returns list of length the number of `sa_items`, each a `ts` object;
- if `x` is a workspace object, `get_ts(x)` returns list of length the number of `multiprocessing`, each element containing a list of `ts` object.

## See Also

Other functions to get informations from a workspace, multiprocessing or sa\_item: [count](#), [get\\_model](#), [get\\_name](#).

## Examples

```
sa_x13 <- x13(ipi_c_eu[, "FR"], spec = "RSA5c")

wk <- new_workspace()
mp <- new_multiprocessing(wk, "sa1")
add_sa_item(wk, "sa1", sa_x13, "X13")
sa_item <- get_object(mp, 1)

# Extracting from a SA:
get_ts(sa_x13) # Returns the ts object ipi_c_eu[, "FR"]

# Extracting from a sa_item:
get_ts(sa_item) # Returns the ts object ipi_c_eu[, "FR"]

# Extracting from a multiprocessing:
# Returns a list of length 1 named "X13" containing the ts object ipi_c_eu[, "FR"]:
get_ts(mp)

# Extracting from a workspace:
# Returns a list of length 1 named "sa1" containing a list
# of length 1 named "X13" containing the ts object ipi_c_eu[, "FR"]
get_ts(wk)
```

---

ipi\_c\_eu

*Industrial Production Indices in manufacturing in the European Union*

---

## Description

A dataset containing on monthly industrial production indices in manufacturing in the European Union (from sts\_inpr\_m dataset of Eurostat). Data are based 100 in 2015 and are unadjusted, i.e. neither seasonally adjusted nor calendar adjusted.

## Usage

```
ipi_c_eu
```

## Format

A monthly ts object from january 1990 to december 2017 with 37 variables.

**Details**

The dataset contains 37 time series corresponding to the following geographical area

EU28	European Union (current composition)
EU27_2019	European Union (without United Kingdom)
EA19	Euro area (19 countries)
BE	Belgium
BG	Bulgaria
CZ	Czechia
DK	Denmark
DE	Germany (until 1990 former territory of the FRG)
EE	Estonia
IE	Ireland
EL	Greece
ES	Spain
FR	France
HR	Croatia
IT	Italy
CY	Cyprus
LV	Latvia
LT	Lithuania
LU	Luxembourg
HU	Hungary
MT	Malta
NL	Netherlands
AT	Austria
PL	Poland
PT	Portugal
RO	Romania
SI	Slovenia
SK	Slovakia
FI	Finland
SE	Sweden
UK	United Kingdom
NO	Norway
ME	Montenegro
MK	Former Yugoslav Republic of Macedonia, the
RS	Serbia
TR	Turkey
BA	Bosnia and Herzegovina

## Description

`get_dictionary` returns the indicators that can be extracted from "jSA" objects, `get_indicators` extract a list of indicators and "jSA2R" returns returns the corresponding "SA" or a "regarima" object.

## Usage

```
get_dictionary(x)

get_indicators(x, ...)

jSA2R(x, userdefined = NULL)
```

## Arguments

<code>x</code>	a "jSA" object.
<code>...</code>	characters containing the names of the indicators to extract.
<code>userdefined</code>	userdefined vector with characters for additional output variables (see <a href="#">user_defined_variables</a> ). Only used for "SA" objects.

## Details

A "jSA" object is a list with three elements:

- "result": the Java object with the results of a seasonal adjustment or a pre-adjustment method.
- "spec": the Java object with the specification of a seasonal adjustment or a pre-adjustment method.
- "dictionary": the Java object with dictionary of a seasonal adjustment or a pre-adjustment method. In particular, it contains all the user-defined regressors.

`get_dictionary` returns the list of indicators that can be extracted from a jSA object by the function `get_indicators`.

`jSA2R` returns the corresponding formatted seasonal adjustment ("SA" object) or RegARIMA ("regarima" object) model.

## Value

`get_dictionary` a vector of characters, `get_indicators` returns a list containing the indicators that are extracted and `jSA2R` returns a "SA" or a "regarima" object.

## Examples

```
myseries <- ipi_c_eu[, "FR"]
mysa <- jx13(myseries, spec = "RSA5c")
get_dictionary(mysa)

get_indicators(mysa, "decomposition.b2", "decomposition.d10")
```

```
# To convert to the R object
jSA2R(mysa)
```

---

load_workspace	<i>Load a 'JDemetra+' workspace</i>
----------------	-------------------------------------

---

### Description

Function to load a 'JDemetra+' workspace.

### Usage

```
load_workspace(file)
```

### Arguments

file                    the path to the 'JDemetra+' workspace to load. By default a dialog box opens.

### Value

An object of class "workspace".

### See Also

[save\\_workspace](#), [get\\_model](#)

---

new_workspace	<i>Create a workspace or a multi-processing</i>
---------------	---

---

### Description

Functions to create a 'JDemetra+' workspace (`new_workspace()`) add a multi-processing to it (`new_multiprocessing()`).

### Usage

```
new_workspace()
```

```
new_multiprocessing(workspace, name)
```

### Arguments

workspace            a workspace object

name                    character name of the new multiprocessing

**Value**

`new_workspace()` returns an object of class `workspace` and `new_multiprocessing()` returns an object of class `multiprocessing`.

**See Also**

[load\\_workspace](#), [save\\_workspace](#), [add\\_sa\\_item](#)

**Examples**

```
# Create and export a empty 'JDemetra+' workspace
wk <- new_workspace()
mp <- new_multiprocessing(wk, "sa1")
```

---

plot

*Plotting regarima, decomposition or final results of SA*

---

**Description**

Plotting methods for the S3 class objects around the seasonal adjustment: "regarima" for `RegARIMA`, "decomposition\_X11" and "decomposition\_SEATS" for the decomposition with X13 and TRAMO-SEATS, "final" for the final SA results and "SA" for the entire seasonal adjustment object. The function `plot.SA` just calls the function `plot.final`.

**Usage**

```
## S3 method for class 'regarima'
plot(x, which = 1:6, caption = list("Residuals",
  "Histogram of residuals", "Normal Q-Q", "ACF of residuals",
  "PACF of residuals", "Decomposition", list("Y linearised",
  "Calendar effects", "Outliers effects"))[sort(which)],
  ask = prod(par("mfcol")) < length(which) && dev.interactive(), ...)

## S3 method for class 'decomposition_X11'
plot(x, first_date, last_date,
  caption = "S-I ratio", ...)

## S3 method for class 'decomposition_SEATS'
plot(x, first_date, last_date,
  caption = "S-I ratio", ...)

## S3 method for class 'final'
plot(x, first_date, last_date, forecast = TRUE,
  type_chart = c("sa-trend", "cal-seas-irr"), caption = c(`sa-trend` =
  "Y, Sa, trend", `cal-seas-irr` = "Cal., sea., irr.")[type_chart],
```

```
ask = length(type_chart) > 1 && dev.interactive(), ...)
```

```
## S3 method for class 'SA'
```

```
plot(x, ...)
```

### Arguments

x	the object to plot.
which	vector with numerics specifying which graphs should be plotted: (1) "Residuals", (2) "Histogram of residuals", (3) "Normal Q-Q", (4) "ACF of residuals", (5) "PACF of residuals", (6) "Decomposition", (7) "Decomposition - zoom".
caption	list or character with the graphs titles.
ask	logicals. If TRUE, the user will in future be prompted before a new graphical page is started.
...	other parameters.
first_date	the first date to start the plot. If missing the plot starts at the beginning of the time-series.
last_date	the last date to end the plot. If missing the plot ends at the end of the time-series (eventually, including forecast).
forecast	logical indicating if forecasts should be included in the plot. If TRUE the forecast is plotted.
type_chart	character vector indicating which type of chart to plot.

### Examples

```
myseries <- ipi_c_eu[, "FR"]
mysa <- x13(myseries, spec = c("RSA5c"))
# RegArima
plot(mysa$regarima) # 6 graphics are plotted by default
# To only plot one graphic (here the residuals) changing the title:
plot(mysa$regarima, which = 1, caption = "Plot of residuals")
plot(mysa$regarima, which = 7)

# Decomposition
plot(mysa$decomposition) # To plot the S-I ratio
plot(mysa$decomposition, first_date = c(2010, 1)) # To start the plot in January 2010

# Final
plot(mysa$final) # 2 graphics are plotted by default
# To only plot one graphic (here raw data, seasonal adjusted data and trend),
# changing the last date and the title
plot(mysa$final, last_date = c(2000, 1),
      caption = "Results", type_chart = "sa-trend")
```

regarima

*RegARIMA model, pre-adjustment in X13 and TRAMO-SEATS***Description**

regarima/regarima\_x13/regarima\_tramoseats decomposes the time series in a linear deterministic component and in a stochastic component. The deterministic part of the series can contain outliers, calendar effects and regression effects. The stochastic part is defined by a seasonal multiplicative ARIMA model, as discussed by BOX, G.E.P., and JENKINS, G.M. (1970). jregarima/jregarima\_x13/jregarima\_tramoseats does the same computation but returns the Java objects without formatting the output

**Usage**

```
jregarima(series, spec = NA)

regarima_tramoseats(series, spec = c("TRfull", "TR0", "TR1", "TR2",
  "TR3", "TR4", "TR5"))

regarima_x13(series, spec = c("RG5c", "RG0", "RG1", "RG2c", "RG3",
  "RG4c"))

regarima(series, spec = NA)

regarima_tramoseats(series, spec = c("TRfull", "TR0", "TR1", "TR2",
  "TR3", "TR4", "TR5"))

regarima_x13(series, spec = c("RG5c", "RG0", "RG1", "RG2c", "RG3",
  "RG4c"))
```

**Arguments**

series	a univariate time series
spec	model specification. For the function: <ul style="list-style-type: none"> <li>• regarima, object of class c("regarima_spec", "X13") or c("regarima_spec", "TRAMO_SEATS") See functions <a href="#">regarima_spec_x13</a> and <a href="#">regarima_spec_tramoseats</a>.</li> <li>• regarima_x13, predefined X13 'JDemetra+' model specification (see <i>Details</i>). The default is "RG5c".</li> <li>• regarima_tramoseats, predefined TRAMO-SEATS 'JDemetra+' model specification (see <i>Details</i>). The default is "TRfull".</li> </ul>

**Details**

In the X13 and TRAMO-SEATS seasonal adjustment the first step consists of pre-adjusting the original series with a RegARIMA model, where the original series is corrected for any deterministic effects and missing observations. This step is also referred as linearization of the original series.

The RegARIMA model (model with ARIMA errors) is specified as below.

$$z_t = y_t\beta + x_t$$

where:

- $z_t$  - is the original series;
- $\beta = (\beta_1, \dots, \beta_n)$  - a vector of regression coefficients;
- $y_t = (y_{1t}, \dots, y_{nt})$  -  $n$  regression variables (outliers, calendar effects, user-defined variables);
- $x_t$  - a disturbance that follows the general ARIMA process:  $\phi(B)\delta(B)x_t = \theta(B)a_t$ ;  $\phi(B)$ ,  $\delta(B)$  and  $\theta(B)$  are the finite polynomials in  $B$ ;  $a_t$  is a white-noise variable with zero mean and a constant variance.

The polynomial  $\phi(B)$  is a stationary autoregressive (AR) polynomial in  $B$ , which is a product of the stationary regular AR polynomial in  $B$  and the stationary seasonal polynomial in  $B^s$ :

$$\phi(B) = \phi_p(B)\Phi_{bp}(B^s) = (1 + \phi_1B + \dots + \phi_pB^p)(1 + \Phi_1B^s + \dots + \Phi_{bp}B^{bps})$$

where:

- $p$  - number of regular AR terms (here and in 'JDemetra+'  $p \leq 3$ );
- $bp$  - number of seasonal AR terms (here and in 'JDemetra+'  $bp \leq 1$ );
- $s$  - number of observations per year (frequency of the time series).

The polynomial  $\theta(B)$  is an invertible moving average (MA) polynomial in  $B$ , which is a product of the invertible regular MA polynomial in  $B$  and the invertible seasonal MA polynomial in  $B^s$ :

$$\theta(B) = \theta_q(B)\Theta_{bq}(B^s) = (1 + \theta_1B + \dots + \theta_qB^q)(1 + \Theta_1B^s + \dots + \Theta_{bq}B^{bqs})$$

where:

- $q$  - number of regular MA terms (here and in 'JDemetra+'  $q \leq 3$ );
- $bq$  - number of seasonal MA terms (here and in 'JDemetra+'  $bq \leq 1$ );

The polynomial  $\delta(B)$  is the non-stationary AR polynomial in  $B$  (unit roots):

$$\delta(B) = (1 - B)^d(1 - B^s)^{d_s}$$

where:

- $d$  - regular differencing order (here and in 'JDemetra+'  $d \leq 1$ );
- $d_s$  - seasonal differencing order (here and in 'JDemetra+'  $d_s \leq 1$ );

Notations used for AR and MA processes, model denoted as ARIMA  $(P, D, Q)(BP, BD, BQ)$ , are consistent with those in 'JDemetra+'.

As regards the available predefined 'JDemetra+' X13 and TRAMO-SEATS model specifications, they are described in the tables below.

### X13:

Identifier	Log/level detection	Outliers detection	Calendar effects	ARIMA
RG0	NA	NA	NA	Airline(+mean)
RG1	automatic	AO/LS/TC	NA	Airline(+mean)
RG2c	automatic	AO/LS/TC	2 td vars + Easter	Airline(+mean)
RG3	automatic	AO/LS/TC	NA	automatic
RG4c	automatic	AO/LS/TC	2 td vars + Easter	automatic
RG5c	automatic	AO/LS/TC	7 td vars + Easter	automatic

#### TRAMO-SEATS:

Identifier	Log/level detection	Outliers detection	Calendar effects	ARIMA
TR0	NA	NA	NA	Airline(+mean)
TR1	automatic	AO/LS/TC	NA	Airline(+mean)
TR2	automatic	AO/LS/TC	2 td vars + Easter	Airline(+mean)
TR3	automatic	AO/LS/TC	NA	automatic
TR4	automatic	AO/LS/TC	2 td vars + Easter	automatic
TR5	automatic	AO/LS/TC	7 td vars + Easter	automatic
TRfull	automatic	AO/LS/TC	automatic	automatic

#### Value

`jregarima/jregarima_x13/jregarima_tramoseats` return a [jSA](#) object. It contains the Java objects of the result of the preadjustment method without any formatting. Therefore the computation is faster than with `regarima/regarima_x13/regarima_tramoseats`. The results can be extracted by [get\\_indicators](#).

`regarima/regarima_x13/regarima_tramoseats` return an object of class "regarima" and sub-class "X13" or "TRAMO\_SEATS". `regarima_x13` returns an object of class `c("regarima", "X13")` and `regarima_tramoseats` an object of class `c("regarima", "TRAMO_SEATS")`. For the function `regarima`, the sub-class of the object depends on the used method that is defined by the class of the spec object.

An object of class "regarima" is a list containing the following components:

<code>specification</code>	list with the model specification as defined by the <code>spec</code> argument. See also Value of the <a href="#">regarima_spec_x13</a> and <a href="#">regarima_spec_tramoseats</a> functions.
<code>arma</code>	vector with the orders of the autoregressive (AR), moving average (MA), seasonal AR and seasonal MA processes, as well as with the regular and seasonal differencing orders (P,D,Q) (BP,BD,BQ).
<code>arma.coefficients</code>	matrix with the regular and seasonal AR and MA coefficients. The matrix contains the estimated coefficients, standard errors and t-statistics values. The estimated coefficients can be also extracted with the function <a href="#">coef</a> (the output includes also the regression coefficients).
<code>regression.coefficients</code>	matrix with the regression variables (i.e.: mean, calendar effect, outliers and user-defined regressors) coefficients. The matrix contains the estimated coefficients, standard errors and t-statistics values. The estimated coefficients can be also extracted with the function <a href="#">coef</a> (output includes also the arima coefficients).

loglik	matrix containing the log-likelihood of the RegARIMA model as well as the associated model selection criteria statistics (AIC, AICC, BIC and BICC) and parameters (np = number of parameters in the likelihood, neffectiveobs = number of effective observations in the likelihood). These statistics can be also extracted with the function <code>logLik</code> .
model	list containing the information on the model specification after its estimation ( <code>spec_rslt</code> ), as well as the decomposed elements of the input series ( <code>ts</code> matrix, <code>effects</code> ). The model specification includes the information on the estimation method ( <code>Model</code> ) and time span ( <code>T.span</code> ), whether the original series was log transformed ( <code>Log</code> transformation) and details on the regression part of the RegARIMA model; i.e. if it includes a Mean, Trading days effects (if yes, it provides the number of regressors), Leap year effect, Easter effect and whether outliers were detected ( <code>Outliers</code> ; if yes, it provides the number of outliers). The decomposed elements of the input series contain the linearised series ( <code>y_lin</code> ) and the deterministic components; i.e.: trading days effect ( <code>tde</code> ), Easter effect ( <code>ee</code> ), other moving holidays effect ( <code>omhe</code> ) and outliers effect (total - <code>out</code> , related to irregular - <code>out_i</code> , related to trend - <code>out_t</code> , related to seasonal - <code>out_s</code> ).
residuals	the residuals (time series). They can be also extracted with the function <code>residuals</code> .
residuals.stat	List containing statistics on the RegARIMA residuals. It provides residuals standard error ( <code>st.error</code> ) and results for the tests on the normality, independence and linearity of the residuals ( <code>tests</code> ) - object of class <code>c("regarima_rtests", "data.frame")</code> .
forecast	<code>ts</code> matrix containing the forecast of the original series ( <code>fcst</code> ) and it's standard error ( <code>fcsterr</code> ).

*RegARIMA model specification, pre-adjustment in TRAMO-SEATS*

---

## Description

Function to create (and/or modify) a `c("regarima_spec", "TRAMO_SEATS")` class object with the RegARIMA model specification for the TRAMO-SEATS method. The object can be created from a predefined 'JDemetra+' model specification (a character), a previous specification (`c("regarima_spec", "TRAMO_SEATS")` object) or a TRAMO-SEATS RegARIMA model (`c("regarima", "TRAMO_SEATS")`).

**Usage**

```
regarima_spec_tramoseats(spec = c("TRfull", "TR0", "TR1", "TR2", "TR3",
  "TR4", "TR5"), preliminary.check = NA, estimate.from = NA_character_,
  estimate.to = NA_character_, estimate.first = NA_integer_,
  estimate.last = NA_integer_, estimate.exclFirst = NA_integer_,
  estimate.exclLast = NA_integer_, estimate.tol = NA_integer_,
  estimate.eml = NA, estimate.urfinal = NA_integer_,
  transform.function = c(NA, "Auto", "None", "Log"),
  transform.fct = NA_integer_, usrdef.outliersEnabled = NA,
  usrdef.outliersType = NA, usrdef.outliersDate = NA,
  usrdef.outliersCoef = NA, usrdef.varEnabled = NA, usrdef.var = NA,
  usrdef.varType = NA, usrdef.varCoef = NA, tradingdays.mauto = c(NA,
  "Unused", "FTest", "WaldTest"), tradingdays.pftd = NA_integer_,
  tradingdays.option = c(NA, "TradingDays", "WorkingDays", "UserDefined",
  "None"), tradingdays.leapyear = NA,
  tradingdays.stocktd = NA_integer_, tradingdays.test = c(NA,
  "Separate_T", "Joint_F", "None"), easter.type = c(NA, "Unused",
  "Standard", "IncludeEaster", "IncludeEasterMonday"),
  easter.julian = NA, easter.duration = NA_integer_,
  easter.test = NA, outlier.enabled = NA,
  outlier.from = NA_character_, outlier.to = NA_character_,
  outlier.first = NA_integer_, outlier.last = NA_integer_,
  outlier.exclFirst = NA_integer_, outlier.exclLast = NA_integer_,
  outlier.ao = NA, outlier.tc = NA, outlier.ls = NA,
  outlier.so = NA, outlier.usedefcv = NA, outlier.cv = NA_integer_,
  outlier.eml = NA, outlier.tcrate = NA_integer_,
  automdl.enabled = NA, automdl.acceptdefault = NA,
  automdl.cancel = NA_integer_, automdl.ub1 = NA_integer_,
  automdl.ub2 = NA_integer_, automdl.armalimit = NA_integer_,
  automdl.reducecv = NA_integer_, automdl.ljungboxlimit = NA_integer_,
  automdl.compare = NA, arima.mu = NA, arima.p = NA_integer_,
  arima.d = NA_integer_, arima.q = NA_integer_,
  arima.bp = NA_integer_, arima.bd = NA_integer_,
  arima.bq = NA_integer_, arima.coefEnabled = NA, arima.coef = NA,
  arima.coefType = NA, fcst.horizon = NA_integer_, object)
```

**Arguments**

**spec** model specification. It can be a character of predefined 'JDemetra+' model specification (see *Details*), an object of class `c("regarima_spec", "TRAMO_SEATS")` or an object of class `c("regarima", "TRAMO_SEATS")`. The default is "TRfull".

The time span of the series to be used for the estimation of the RegARima model coefficients (default from 1900-01-01 to 2020-12-31) is controlled by the following six variables: `estimate.from`, `estimate.to`, `estimate.first`, `estimate.last`, `estimate.exclFirst` and `estimate.exclLast`; where `estimate.from` and `estimate.to` have priority over remaining span control variables, `estimate.last` and `estimate.first` have priority over `estimate.exclFirst` and `estimate.exclLast`, and `estimate.last` has priority over `estimate.first`.

<code>preliminary.check</code>	boolean to check the quality of the input series and exclude highly problematic ones: e.g. these with a number of identical observations and/or missing values above pre-specified threshold values.
<code>estimate.from</code>	character in format "YYYY-MM-DD" indicating the start of the time span (e.g. "1900-01-01"). Can be combined with <code>estimate.to</code> .
<code>estimate.to</code>	character in format "YYYY-MM-DD" indicating the end of the time span (e.g. "2020-12-31"). Can be combined with <code>estimate.from</code> .
<code>estimate.first</code>	numeric specifying the number of periods considered at the beginning of the series.
<code>estimate.last</code>	numeric specifying the number of periods considered at the end of the series.
<code>estimate.exclFirst</code>	numeric specifying the number of periods excluded at the beginning of the series. Can be combined with <code>estimate.exclLast</code> .
<code>estimate.exclLast</code>	numeric specifying the number of periods excluded at the end of the series. Can be combined with <code>estimate.exclFirst</code> .
<code>estimate.tol</code>	numeric, convergence tolerance. The absolute changes in the log-likelihood function are compared to this value to check for the convergence of the estimation iterations.
<code>estimate.eml</code>	logicals, exact maximum likelihood estimation. If TRUE the program performs an exact maximum likelihood estimation. If FASLE the Unconditional Least Squares method is used.
<code>estimate.urfinal</code>	numeric, final unit root limit. The threshold value for the final unit root test for identification of differencing orders. If the magnitude of an AR root for the final model is less than this number, a unit root is assumed, the order of the AR polynomial is reduced by one, and the appropriate order of the differencing (non-seasonal, seasonal) is increased.
<code>transform.function</code>	transformation of the input series: "None" - no transformation of the series; "Log" - takes the log of the series; "Auto" - the program tests for the log-level specification.
<code>transform.fct</code>	numeric controlling the bias in the log/level pre-test: <code>transform.fct &gt; 1</code> favours levels, <code>transform.fct &lt; 1</code> favours logs. Considered only when <code>transform.function</code> is set to "Auto".  Control variables for the pre-specified outliers. The pre-specified outliers are used in the model only if they are enabled ( <code>usrdef.outliersEnabled=TRUE</code> ) and the outliers' type ( <code>usrdef.outliersType</code> ) and date ( <code>usrdef.outliersDate</code> ) are provided.
<code>usrdef.outliersEnabled</code>	logicals. If TRUE the program uses the pre-specified outliers.
<code>usrdef.outliersType</code>	vector defining the outliers' type. Possible types are: ("A0") - additive, ("LS") - level shift, ("TC") - transitory change, ("S0") - seasonal outlier. E.g.: <code>usrdef.outliersType =c("A0",</code>

`usrdef.outliersDate` vector defining the outliers' date. The dates should be characters in format "YYYY-MM-DD". E.g.: `usrdef.outliersDate=c("2009-10-01", "2005-02-01", "2003-04-01")`.

`usrdef.outliersCoef` vector providing fixed coefficients for the outliers. The coefficients can't be fixed if `transform.function` is set to "Auto" - the series transformation need to be pre-defined. E.g.: `usrdef.outliersCoef=c(200,170,20)`.

Control variables for the user-defined variables:

`usrdef.varEnabled` logicals. If TRUE the program uses the user-defined variables.

`usrdef.var` time series (ts) or matrix of time series (mts) with the user-defined variables.

`usrdef.varType` vector of character(s) defining the user-defined variables component type. Possible types are: "Undefined", "Series", "Trend", "Seasonal", "SeasonallyAdjusted", "Irregular". The type "Calendar" has to be used with `tradingdays.option = "UserDefined"` to use user-defined calendar regressors. If not specified, the program will assign the "Undefined" type.

`usrdef.varCoef` vector providing fixed coefficients for the user-defined variables. The coefficients can't be fixed if `transform.function` is set to "Auto" - the series transformation need to be pre-defined.

`tradingdays.mauto` defines whether the calendar effects should be added to the model manually ("Unused") or automatically. In the automatic selection, the choice of the number of calendar variables can be based on the F-Test ("FTest") or the Wald Test ("WaldTest"); the model with higher F value is chosen, provided that it is higher than `tradingdays.pftd`.

`tradingdays.pftd` numeric. P-value applied in the test specified by the automatic parameter (`tradingdays.mauto`) to assess the significance of the pre-tested calendar effects variables and whether they should be included in the RegArima model.

Control variables for the manual selection of calendar effects variables (`tradingdays.mauto` is set to "Unused"):

`tradingdays.option` defines the type of the trading days regression variables: "TradingDays" - six day-of-the-week regression variables; "WorkingDays" - one working/non-working day contrast variable; "None" - no correction for trading days and working days effects; "UserDefined" - user-defined trading days regressors (regressors have to be defined by the `usrdef.var` argument with `usrdef.varType` set to "Calendar" and `usrdef.varEnabled = TRUE`). "None" has also to be chosen for the "day-of-week effects" correction (`tradingdays.stocktd` to be modified accordingly).

`tradingdays.leapyear` logicals. Specifies if the leap-year correction should be included. If TRUE the model includes the leap-year effect.

`tradingdays.stocktd` numeric indicating the day of the month when inventories and other stock are reported (to denote the last day of the month set the variable to 31). Modifications of this variable are taken into account only when `tradingdays.option` is set to "None".

<code>tradingdays.test</code>	defines the pre-tests of the trading day effects: "None" - calendar variables are used in the model without pre-testing; "Separate_T" - a t-test is applied to each trading day variable separately and the trading day variables are included in the RegArima model if at least one t-statistic is greater than 2.6 or if two t-statistics are greater than 2.0 (in absolute terms); "Joint_F" - a joint F-test of significance of all the trading day variables. The trading day effect is significant if the F statistic is greater than 0.95.
<code>easter.type</code>	specifies the presence and the length of the Easter effect: "Unused" - Easter effect is not considered; "Standard" - influences the period of n days strictly before Easter Sunday; "IncludeEaster" - influences the entire period (n) up to and including Easter Sunday; "IncludeEasterMonday" - influences the entire period (n) up to and including Easter Monday.
<code>easter.julian</code>	logicals. If TRUE the program uses the Julian Easter (expressed in Gregorian calendar).
<code>easter.duration</code>	numeric indicating the duration of the Easter effect (length in days, between 1 and 15).
<code>easter.test</code>	logicals. If TRUE the program performs a t-test for the significance of the Easter effect. The Easter effect is considered as significant if the modulus of t-statistic is greater than 1.96.
<code>outlier.enabled</code>	logicals. If TRUE the automatic detection of outliers is enabled in the defined time span. The time span of the series to be searched for outliers (default from 1900-01-01 to 2020-12-31) is controlled by the following six variables: <code>outlier.from</code> , <code>outlier.to</code> , <code>outlier.first</code> and <code>outlier.exclLast</code> ; where <code>outlier.from</code> and <code>outlier.to</code> have priority over remaining span control variables, <code>outlier.last</code> and <code>outlier.first</code> have priority over <code>outlier.exclFirst</code> and <code>outlier.exclLast</code> , and <code>outlier.last</code> has priority over <code>outlier.first</code> .
<code>outlier.from</code>	character in format "YYYY-MM-DD" indicating the start of the time span (e.g. "1900-01-01"). Can be combined with <code>outlier.to</code> .
<code>outlier.to</code>	character in format "YYYY-MM-DD" indicating the end of the time span (e.g. "2020-12-31"). Can be combined with <code>outlier.from</code> .
<code>outlier.first</code>	numeric specifying the number of periods considered at the beginning of the series.
<code>outlier.last</code>	numeric specifying the number of periods considered at the end of the series.
<code>outlier.exclFirst</code>	numeric specifying the number of periods excluded at the beginning of the series. Can be combined with <code>outlier.exclLast</code> .
<code>outlier.exclLast</code>	numeric specifying the number of periods excluded at the end of the series. Can be combined with <code>outlier.exclFirst</code> .
<code>outlier.ao</code>	logicals. If TRUE the automatic detection of additive outliers is enabled ( <code>outlier.enabled</code> must be also set to TRUE).

outlier.tc	logicals. If TRUE the automatic detection of transitory changes is enabled (outlier.enabled must be also set to TRUE).
outlier.ls	logicals. If TRUE the automatic detection of level shifts is enabled (outlier.enabled must be also set to TRUE).
outlier.so	logicals. If TRUE the automatic detection of seasonal outliers is enabled (outlier.enabled must be also set to TRUE).
outlier.usedefcv	logicals. If TRUE the critical value for the outliers' detection procedure is automatically determined by the number of observations in the outlier detection time span. If FALSE the procedure uses the inputted critical value (outlier.cv).
outlier.cv	numeric. Inputted critical value for the outliers' detection procedure. The modification of this variable is taken in to account only when outlier.usedefcv is set to FALSE.
outlier.eml	logicals, exact likelihood estimation method. Controls the method applied for a parameter estimation in the intermediate steps of the automatic detection and correction of outliers. If TRUE an exact likelihood estimation method is used, when FALSE the fast Hannan-Rissanen method is used.
outlier.tcrate	numeric. The rate of decay for the transitory change outlier.
automdl.enabled	logicals. If TRUE the automatic modelling of the ARIMA model is enabled. If FALSE the parameters of the ARIMA model can be specified. Control variables for the automatic modelling of the ARIMA model (automdl.enabled is set to TRUE):
automdl.acceptdefault	logicals. If TRUE the default model (ARIMA(0,1,1)(0,1,1)) may be chosen in the first step of the automatic model identification. If the Ljung-Box Q statistics for the residuals is acceptable, the default model is accepted and no further attempt will be made to identify any other.
automdl.cancel	numeric, cancelation limit. If the difference in moduli of an AR and an MA roots (when estimating ARIMA(1,0,1)(1,0,1) models in the second step of the automatic identification of the differencing orders) is smaller than cancelation limit, the two roots are assumed equal and cancel out.
automdl.ub1	numeric, first unit root limit. It is the threshold value for the initial unit root test in the automatic differencing procedure. When one of the roots in the estimation of the ARIMA(2,0,0)(1,0,0) plus mean model, performed in the first step of the automatic model identification procedure, is larger than first unit root limit in modulus, it is set equal to unity.
automdl.ub2	numeric, second unit root limit. When one of the roots in the estimation of the ARIMA(1,0,1)(1,0,1) plus mean model, which is performed in the second step of the automatic model identification procedure, is larger than second unit root limit in modulus, it is checked if there is a common factor in the corresponding AR and MA polynomials of the ARMA model that can be cancelled (see automdl.cancel). If there is no cancellation, the AR root is set equal to unity (i.e. the differencing order changes).

<code>automdl.armalimit</code>	numeric, arma limit. It is the threshold value for t-statistics of ARMA coefficients and constant term used for the final test of model parsimony. If the highest order ARMA coefficient has a t-value less than this value in magnitude, the order of the model is reduced. Also if the constant term has a t-value less than arma limit in magnitude, it is removed from the set of regressors.
<code>automdl.reducecv</code>	numeric, ReduceCV. The percentage by which the outlier's critical value will be reduced when an identified model is found to have a Ljung-Box statistic with an unacceptable confidence coefficient. The parameter should be between 0 and 1, and will only be active when automatic outlier identification is enabled. The reduced critical value will be set to $(1-\text{ReduceCV}) \times \text{CV}$ , where CV is the original critical value.
<code>automdl.ljungboxlimit</code>	numeric, Ljung Box limit. Acceptance criterion for the confidence intervals of the Ljung-Box Q statistic. If the LjungBox Q statistics for the residuals of a final model is greater than Ljung Box limit, the model is rejected, the outlier critical value is reduced, and model and outlier identification (if specified) is redone with a reduced value.
<code>automdl.compare</code>	<p>logicals. If TRUE the program compares the model identified by the automatic procedure to the default model (ARIMA(0,1,1)(0,1,1)) and the model with the best fit is selected. Criteria considered are residual diagnostics, the model structure and the number of outliers.</p> <p>Control variables for the non-automatic modelling of the ARIMA model (<code>automdl.enabled</code> is set to FALSE):</p>
<code>arima.mu</code>	logicals. If TRUE, the mean is considered as part of the ARIMA model.
<code>arima.p</code>	numeric. The order of the non-seasonal autoregressive (AR) polynomial.
<code>arima.d</code>	numeric. Regular differencing order.
<code>arima.q</code>	numeric. The order of the non-seasonal moving average (MA) polynomial.
<code>arima.bp</code>	numeric. The order of the seasonal autoregressive (AR) polynomial.
<code>arima.bd</code>	numeric. Seasonal differencing order.
<code>arima.bq</code>	<p>numeric. The order of the seasonal moving average (MA) polynomial.</p> <p>Control variables for the user-defined ARMA coefficients. Coefficients can be defined for the regular and seasonal autoregressive (AR) polynomials and moving average (MA) polynomials. The model considers the coefficients only if the procedure for their estimation (<code>arima.coefType</code>) is provided, and the number of provided coefficients matches the sum of (regular and seasonal) AR and MA orders (p, q, bp, bq).</p>
<code>arima.coefEnabled</code>	logicals. If TRUE the program uses the user-defined ARMA coefficients.
<code>arima.coef</code>	vector providing the coefficients for the regular and seasonal AR and MA polynomials. The length of the vector must equal the sum of the regular and seasonal AR and MA orders. The coefficients shall be provided in the order: regular AR ( <i>Phi</i> - p elements), regular MA ( <i>Theta</i> - q elements), seasonal AR ( <i>BPhi</i> - bp elements) and seasonal MA ( <i>BTheta</i> - bq elements). E.g.: <code>arima.coef=c(0.6,0.7)</code> with <code>arima.p=1</code> , <code>arima.q=0</code> , <code>arima.bp=1</code> and <code>arima.bq=0</code> .

- `arma.coefType` vector defining ARMA coefficients estimation procedure. Possible procedures are: "Undefined" - no use of user-defined input (i.e. coefficients are estimated), "Fixed" - fixes the coefficients at the value provided by the user, "Initial" - the value defined by the user is used as initial condition. For orders for which the coefficients shall not be defined, the `arma.coef` can be set to NA or 0 or the `arma.coefType` can be set to "Undefined". E.g.: `arma.coef = c(-0.8,-0.6,NA)`, `arma.coefType = c("Fixed","Fixed","Undefined")`.
- `fcst.horizon` numeric, forecasts horizon. Length of the forecasts generated by the RegARIMA model in periods (positive values) or years (negative values). By default the program generates two years forecasts (`fcst.horizon` set to -2).
- `object` deprecated argument.

**Details**

The available predefined 'JDemetra+' model specifications are described in the table below.

Identifier	Log/level detection	Outliers detection	Calendar effects	ARIMA
TR0	NA	NA	NA	Airline(+mean)
TR1	automatic	AO/LS/TC	NA	Airline(+mean)
TR2	automatic	AO/LS/TC	2 td vars + Easter	Airline(+mean)
TR3	automatic	AO/LS/TC	NA	automatic
TR4	automatic	AO/LS/TC	2 td vars + Easter	automatic
TR5	automatic	AO/LS/TC	7 td vars + Easter	automatic
TRfull	automatic	AO/LS/TC	automatic	automatic

**Value**

A list of class `c("regarima_spec", "TRAMO_SEATS")` with the below components. Each component refers to different part of the RegARIMA model specification, mirroring the arguments of the function (for details see arguments description). Each of the lowest-level component (except span, pre-specified outliers, user-defined variables and pre-specified ARMA coefficients) is structured within a data frame with columns denoting different variables of the model specification and rows referring to: first row - base specification, as provided within the argument `spec`; second row - user modifications as specified by the remaining arguments of the function (e.g.: `arma.d`); and third row - final model specification, values that will be used in the function `regarima`. The final specification (third row) shall include user modifications (row two) unless they were wrongly specified. The pre-specified outliers, user-defined variables and pre-specified ARMA coefficients consist of a list with the Predefined (base model specification) and Final values.

- `estimate` data frame. Variables referring to: `span` - time span for the model estimation, `tolerance` - argument `estimate.tol`, `exact_ml` - argument `estimate.eml`, `urfinal` - argument `estimate.urfinal`. The final values can be also accessed with the function `s_estimate`.
- `transform` data frame. Variables referring to: `tfunction` - argument `transform.function`, `fct` - argument `transform.fct`. The final values can be also accessed with the function `s_transform`.
- `regression` list including the information on the user-defined variables (`userdef`), `trading.days` effect and easter effect. The user-defined part includes: `specification` -

	<p>data frame with the information if pre-specified outliers (outlier) and user-defined variables (variables) are included in the model and if fixed coefficients are used (outlier.coef and variables.coef). The final values can be also accessed with the function <code>s_usrdef</code>; outliers - matrixes with the outliers (Predefined and Final). The final outliers can be also accessed with the function <code>s_preOut</code>; and variables - list with the Predefined and Final user-defined variables (series) and its description (description) including the information on the variable type and values of fixed coefficients. The final user-defined variables can be also accessed with the function <code>s_preVar</code>. Within the data frame trading.days variables refer to: automatic - argument tradingdays.mauto, pftd - argument tradingdays.pftd, option - argument tradingdays.option, leapyear - argument tradingdays.leapyear, stocktd - argument tradingdays.stocktd, test - argument tradingdays.test. The final trading.days values can be also accessed with the function <code>s_td</code>. Within the data frame easter variables refer to: type - argument easter.type, julian - argument easter.julian, duration - argument easter.duration, test - argument easter.test. The final easter values can be also accessed with the function <code>s_easter</code>.</p>
outliers	<p>data frame. Variables referring to: ao - argument outlier.ao, tc - argument outlier.tc, ls - argument outlier.ls, so - argument outlier.so, usedefcv - argument outlier.usedefcv, cv - argument outlier.cv, eml - argument outlier.eml, tcrate - argument outlier.tcrate. The final values can be also accessed with the function <code>s_out</code>.</p>
arima	<p>list containing a data frame with the ARIMA settings (specification) and matrixes with the information on the pre-specified ARMA coefficients (coefficients). The matrix Predefined refers to the pre-defined model specification and matrix Final to the final specification. Both matrixes contain the value of the ARMA coefficients and the procedure for its estimation. Within the data frame specification the variable enabled refer to the argument automdl.enabled and all the remaining variables (automdl.acceptdefault, automdl.cancel, automdl.ub1, automdl</p>
forecast	<p>data frame with the forecast horizon (argument fcst.horizon). The final value can be also accessed with the function <code>s_fcst</code>.</p>
span	<p>matrix containing the final time span for the model estimation and outliers' detection. Contains the same information as the variable span in the data frames estimate and outliers. The matrix can be also accessed with the function <code>s_span</code>.</p>

regarima\_spec\_x13

*RegARIMA model specification, pre-adjustment in X13*

---

## Description

Function to create (and/or modify) a `c("regarima_spec", "X13")` class object with the RegARIMA model specification for the X13 method. The object can be created from a predefined 'JDemetra+' model specification (a character), a previous specification (`c("regarima_spec", "X13")` object) or a X13 RegARIMA model (`c("regarima", "X13")`).

## Usage

```

regarima_spec_x13(spec = c("RG5c", "RG0", "RG1", "RG2c", "RG3", "RG4c"),
  preliminary.check = NA, estimate.from = NA_character_,
  estimate.to = NA_character_, estimate.first = NA_integer_,
  estimate.last = NA_integer_, estimate.exclFirst = NA_integer_,
  estimate.exclLast = NA_integer_, estimate.tol = NA_integer_,
  transform.function = c(NA, "Auto", "None", "Log"),
  transform.adjust = c(NA, "None", "LeapYear", "LengthOfPeriod"),
  transform.aicdiff = NA_integer_, usrdef.outliersEnabled = NA,
  usrdef.outliersType = NA, usrdef.outliersDate = NA,
  usrdef.outliersCoef = NA, usrdef.varEnabled = NA, usrdef.var = NA,
  usrdef.varType = NA, usrdef.varCoef = NA,
  tradingdays.option = c(NA, "TradingDays", "WorkingDays", "UserDefined",
    "None"), tradingdays.autoadjust = NA, tradingdays.leapyear = c(NA,
    "LeapYear", "LengthOfPeriod", "None"),
  tradingdays.stocktd = NA_integer_, tradingdays.test = c(NA, "Remove",
    "Add", "None"), easter.enabled = NA, easter.julian = NA,
  easter.duration = NA_integer_, easter.test = c(NA, "Add", "Remove",
    "None"), outlier.enabled = NA, outlier.from = NA_character_,
  outlier.to = NA_character_, outlier.first = NA_integer_,

```

```

outlier.last = NA_integer_, outlier.exclFirst = NA_integer_,
outlier.exclLast = NA_integer_, outlier.ao = NA, outlier.tc = NA,
outlier.ls = NA, outlier.so = NA, outlier.usedefcv = NA,
outlier.cv = NA_integer_, outlier.method = c(NA, "AddOne", "AddAll"),
outlier.tcrate = NA_integer_, automdl.enabled = NA,
automdl.acceptdefault = NA, automdl.cancel = NA_integer_,
automdl.ub1 = NA_integer_, automdl.ub2 = NA_integer_,
automdl.mixed = NA, automdl.balanced = NA,
automdl.armalimit = NA_integer_, automdl.reducecv = NA_integer_,
automdl.ljungboxlimit = NA_integer_, automdl.ubfinal = NA_integer_,
arma.mu = NA, arma.p = NA_integer_, arma.d = NA_integer_,
arma.q = NA_integer_, arma.bp = NA_integer_,
arma.bd = NA_integer_, arma.bq = NA_integer_,
arma.coefEnabled = NA, arma.coef = NA, arma.coefType = NA,
fcst.horizon = NA_integer_, object)

```

## Arguments

spec	<p>model specification. It can be a character of predefined 'JDemetra+' model specification (see <i>Details</i>), an object of class <code>c("regarima_spec", "X13")</code> or an object of class <code>c("regarima", "X13")</code>. The default is "RG5c".</p> <p>The time span of the series to be used for the estimation of the RegARIMA model coefficients (default from 1900-01-01 to 2020-12-31) is controlled by the following six variables: <code>estimate.from</code>, <code>estimate.to</code>, <code>estimate.first</code>, <code>estimate.last</code>, <code>estimate.exclFirst</code> and <code>estimate.exclLast</code>; where <code>estimate.from</code> and <code>estimate.to</code> have priority over remaining span control variables, <code>estimate.last</code> and <code>estimate.first</code> have priority over <code>estimate.exclFirst</code> and <code>estimate.exclLast</code>, and <code>estimate.last</code> has priority over <code>estimate.first</code>.</p>
preliminary.check	boolean to check the quality of the input series and exclude highly problematic ones: e.g. these with a number of identical observations and/or missing values above pre-specified threshold values.
estimate.from	character in format "YYYY-MM-DD" indicating the start of the time span (e.g. "1900-01-01"). Can be combined with <code>estimate.to</code> .
estimate.to	character in format "YYYY-MM-DD" indicating the end of the time span (e.g. "2020-12-31"). Can be combined with <code>estimate.from</code> .
estimate.first	numeric specifying the number of periods considered at the beginning of the series.
estimate.last	numeric specifying the number of periods considered at the end of the series.
estimate.exclFirst	numeric specifying the number of periods excluded at the beginning of the series. Can be combined with <code>estimate.exclLast</code> .
estimate.exclLast	numeric specifying the number of periods excluded at the end of the series. Can be combined with <code>estimate.exclFirst</code> .
estimate.tol	numeric, convergence tolerance. The absolute changes in the log-likelihood function are compared to this value to check for the convergence of the estimation iterations.

- `transform.function`  
transformation of the input series: "None" - no transformation of the series; "Log" - takes the log of the series; "Auto" - the program tests for the log-level specification.
- `transform.adjust`  
pre-adjustment of the input series for length of period or leap year effects: "None" - no adjustment; "LeapYear" - leap year effect; "LengthOfPeriod" - length of period. Modifications of this variable are taken into account only when `transform.function` is set to "Log".
- `transform.aicdiff`  
numeric defining the difference in AICC needed to accept no transformation when the automatic transformation selection is chosen (considered only when `transform.function` is set to "Auto").  
Control variables for the pre-specified outliers. The pre-specified outliers are used in the model only if they are enabled (`usrdef.outliersEnabled=TRUE`) and the outliers' type (`usrdef.outliersType`) and date (`usrdef.outliersDate`) are provided.
- `usrdef.outliersEnabled`  
logicals. If TRUE the program uses the pre-specified outliers.
- `usrdef.outliersType`  
vector defining the outliers' type. Possible types are: ("A0") - additive, ("LS") - level shift, ("TC") - transitory change, ("S0") - seasonal outlier. E.g.: `usrdef.outliersType =c("A0"`
- `usrdef.outliersDate`  
vector defining the outliers' date. The dates should be characters in format "YYYY-MM-DD". E.g.: `usrdef.outliersDate=c("2009-10-01", "2005-02-01", "2003-04-01")`.
- `usrdef.outliersCoef`  
vector providing fixed coefficients for the outliers. The coefficients can't be fixed if `transform.function` is set to "Auto" - the series transformation need to be pre-defined. E.g.: `usrdef.outliersCoef=c(200, 170, 20)`.  
Control variables for the user-defined variables:
- `usrdef.varEnabled`  
logicals. If TRUE the program uses the user-defined variables.
- `usrdef.var`  
time series (ts) or matrix of time series (mts) with the user-defined variables.
- `usrdef.varType`  
vector of character(s) defining the user-defined variables component type. Possible types are: "Undefined", "Series", "Trend", "Seasonal", "SeasonallyAdjusted", "Irregular". The type "Calendar" has to be used with `tradingdays.option = "UserDefined"` to use user-defined calendar regressors. If not specified, the program will assign the "Undefined" type.
- `usrdef.varCoef`  
vector providing fixed coefficients for the user-defined variables. The coefficients can't be fixed if `transform.function` is set to "Auto" - the series transformation need to be pre-defined.
- `tradingdays.option`  
defines the type of the trading days regression variables: "TradingDays" - six day-of-the-week regression variables; "WorkingDays" - one working/non-working day contrast variable; "None" - no correction for trading days and

working days effects; "UserDefined" - user-defined trading days regressors (regressors have to be defined by the `usrdef.var` argument with `usrdef.varType` set to "Calendar" and `usrdef.varEnabled = TRUE`). "None" has also to be chosen for the "day-of-week effects" correction (`tradingdays.stocktd` to be modified accordingly).

`tradingdays.autoadjust`

logicals. If TRUE the program corrects automatically for the leap year effect. Modifications of this variable are taken into account only when `transform.function` is set to "Auto".

`tradingdays.leapyear`

option for including the leap-year effect in the model: "LeapYear" - leap year effect; "LengthOfPeriod" - length of period, "None" - no effect included. The leap-year effect can be pre-specified in the model only if the input series was not pre-adjusted (`transform.adjust` set to "None") and the automatic correction for the leap-year effect was not selected (`tradingdays.autoadjust` set to FALSE).

`tradingdays.stocktd`

numeric indicating the day of the month when inventories and other stock are reported (to denote the last day of the month set the variable to 31). Modifications of this variable are taken into account only when `tradingdays.option` is set to "None".

`tradingdays.test`

defines the pre-tests for the significance of the trading day regression variables based on the AICC statistics: "Add" - the trading day variables are not included in the initial regression model but can be added to the RegARIMA model after the test; "Remove" - the trading day variables belong to the initial regression model but can be removed from the RegARIMA model after the test; "None" - the trading day variables are not pre-tested and are included in the model.

`easter.enabled` logicals. If TRUE the program considers the Easter effect in the model.

`easter.julian` logicals. If TRUE the program uses the Julian Easter (expressed in Gregorian calendar).

`easter.duration`

numeric indicating the duration of the Easter effect (length in days, between 1 and 20).

`easter.test`

defines the pre-tests for the significance of the Easter effect based on the t-statistic (Easter effect is considered as significant if the t-statistic is greater than 1.96): "Add" - the Easter effect variable is not included in the initial regression model but can be added to the RegARIMA model after the test; "Remove" - the Easter effect variable belong to the initial regression model but can be removed from the RegARIMA model after the test; "None" - the Easter effect variable is not pre-tested and is included in the model.

`outlier.enabled`

logicals. If TRUE the automatic detection of outliers is enabled in the defined time span.

The time span of the series to be searched for outliers (default from 1900-01-01 to 2020-12-31) is controlled by the following six variables: `outlier.from`, `outlier.to`, `outlier.first` and `outlier.exclLast`; where `outlier.from` and `outlier.to` have priority

	over remaining span control variables, <code>outlier.last</code> and <code>outlier.first</code> have priority over <code>outlier.exclFirst</code> and <code>outlier.exclLast</code> , and <code>outlier.last</code> has priority over <code>outlier.first</code> .
<code>outlier.from</code>	character in format "YYYY-MM-DD" indicating the start of the time span (e.g. "1900-01-01"). Can be combined with <code>outlier.to</code> .
<code>outlier.to</code>	character in format "YYYY-MM-DD" indicating the end of the time span (e.g. "2020-12-31"). Can be combined with <code>outlier.from</code> .
<code>outlier.first</code>	numeric specifying the number of periods considered at the beginning of the series.
<code>outlier.last</code>	numeric specifying the number of periods considered at the end of the series.
<code>outlier.exclFirst</code>	numeric specifying the number of periods excluded at the beginning of the series. Can be combined with <code>outlier.exclLast</code> .
<code>outlier.exclLast</code>	numeric specifying the number of periods excluded at the end of the series. Can be combined with <code>outlier.exclFirst</code> .
<code>outlier.ao</code>	logicals. If TRUE the automatic detection of additive outliers is enabled ( <code>outlier.enabled</code> must be also set to TRUE).
<code>outlier.tc</code>	logicals. If TRUE the automatic detection of transitory changes is enabled ( <code>outlier.enabled</code> must be also set to TRUE).
<code>outlier.ls</code>	logicals. If TRUE the automatic detection of level shifts is enabled ( <code>outlier.enabled</code> must be also set to TRUE).
<code>outlier.so</code>	logicals. If TRUE the automatic detection of seasonal outliers is enabled ( <code>outlier.enabled</code> must be also set to TRUE).
<code>outlier.usedefcv</code>	logicals. If TRUE the critical value for the outliers' detection procedure is automatically determined by the number of observations in the outlier detection time span. If FALSE the procedure uses the inputted critical value ( <code>outlier.cv</code> ).
<code>outlier.cv</code>	numeric. Inputted critical value for the outliers' detection procedure. The modification of this variable is taken into account only when <code>outlier.usedefcv</code> is set to FALSE.
<code>outlier.method</code>	determines how the program successively adds detected outliers to the model. At present only the <code>AddOne</code> method is supported.
<code>outlier.tcrate</code>	numeric. The rate of decay for the transitory change outlier.
<code>automdl.enabled</code>	logicals. If TRUE the automatic modelling of the ARIMA model is enabled. If FALSE the parameters of the ARIMA model can be specified. Control variables for the automatic modelling of the ARIMA model ( <code>automdl.enabled</code> is set to TRUE):
<code>automdl.acceptdefault</code>	logicals. If TRUE the default model (ARIMA(0,1,1)(0,1,1)) may be chosen in the first step of the automatic model identification. If the Ljung-Box Q statistics for the residuals is acceptable, the default model is accepted and no further attempt will be made to identify any other.

- `automdl.cancel` numeric, cancelation limit. If the difference in moduli of an AR and an MA roots (when estimating ARIMA(1,0,1)(1,0,1) models in the second step of the automatic identification of the differencing orders) is smaller than cancelation limit, the two roots are assumed equal and cancel out.
- `automdl.ub1` numeric, first unit root limit. It is the threshold value for the initial unit root test in the automatic differencing procedure. When one of the roots in the estimation of the ARIMA(2,0,0)(1,0,0) plus mean model, performed in the first step of the automatic model identification procedure, is larger than first unit root limit in modulus, it is set equal to unity.
- `automdl.ub2` numeric, second unit root limit. When one of the roots in the estimation of the ARIMA(1,0,1)(1,0,1) plus mean model, which is performed in the second step of the automatic model identification procedure, is larger than second unit root limit in modulus, it is checked if there is a common factor in the corresponding AR and MA polynomials of the ARMA model that can be cancelled (see `automdl.cancel`). If there is no cancellation, the AR root is set equal to unity (i.e. the differencing order changes).
- `automdl.mixed` logicals. The variable controls whether ARIMA models with non-seasonal AR and MA terms or seasonal AR and MA terms will be considered in the automatic model identification procedure. If FALSE a model with AR and MA terms in both the seasonal and non-seasonal parts of the model can be acceptable, provided there are not AR and MA terms in either the seasonal or non-seasonal.
- `automdl.balanced` logicals. If TRUE, the automatic model identification procedure will have a preference for balanced models (i.e. models for which the order of the combined AR and differencing operator is equal to the order of the combined MA operator).
- `automdl.armalimit` numeric, arma limit. It is the threshold value for t-statistics of ARMA coefficients and constant term used for the final test of model parsimony. If the highest order ARMA coefficient has a t-value less than this value in magnitude, the order of the model is reduced. Also if the constant term has a t-value less than arma limit in magnitude, it is removed from the set of regressors.
- `automdl.reducecv` numeric, ReduceCV. The percentage by which the outlier's critical value will be reduced when an identified model is found to have a Ljung-Box statistic with an unacceptable confidence coefficient. The parameter should be between 0 and 1, and will only be active when automatic outlier identification is enabled. The reduced critical value will be set to  $(1-\text{ReduceCV}) \times \text{CV}$ , where CV is the original critical value.
- `automdl.ljungboxlimit` numeric, Ljung Box limit. Acceptance criterion for the confidence intervals of the Ljung-Box Q statistic. If the LjungBox Q statistics for the residuals of a final model is greater than Ljung Box limit, the model is rejected, the outlier critical value is reduced, and model and outlier identification (if specified) is redone with a reduced value.
- `automdl.ubfinal` numeric, final unit root limit. The threshold value for the final unit root test. If the magnitude of an AR root for the final model is less than the final unit

root limit, a unit root is assumed, the order of the AR polynomial is reduced by one, and the appropriate order of the differencing (non-seasonal, seasonal) is increased. The parameter value should be greater than one.

Control variables for the non-automatic modelling of the ARIMA model (`automdl.enabled` is set to FALSE):

<code>arima.mu</code>	logicals. If TRUE, the mean is considered as part of the ARIMA model.
<code>arima.p</code>	numeric. The order of the non-seasonal autoregressive (AR) polynomial.
<code>arima.d</code>	numeric. Regular differencing order.
<code>arima.q</code>	numeric. The order of the non-seasonal moving average (MA) polynomial.
<code>arima.bp</code>	numeric. The order of the seasonal autoregressive (AR) polynomial.
<code>arima.bd</code>	numeric. Seasonal differencing order.
<code>arima.bq</code>	numeric. The order of the seasonal moving average (MA) polynomial.
	Control variables for the user-defined ARMA coefficients. Coefficients can be defined for the regular and seasonal autoregressive (AR) polynomials and moving average (MA) polynomials. The model considers the coefficients only if the procedure for their estimation ( <code>arima.coefType</code> ) is provided, and the number of provided coefficients matches the sum of (regular and seasonal) AR and MA orders ( <code>p</code> , <code>q</code> , <code>bp</code> , <code>bq</code> ).
<code>arima.coefEnabled</code>	logicals. If TRUE the program uses the user-defined ARMA coefficients.
<code>arima.coef</code>	vector providing the coefficients for the regular and seasonal AR and MA polynomials. The length of the vector must equal the sum of the regular and seasonal AR and MA orders. The coefficients shall be provided in the order: regular AR ( <i>Phi</i> - <code>p</code> elements), regular MA ( <i>Theta</i> - <code>q</code> elements), seasonal AR ( <i>BPhi</i> - <code>bp</code> elements) and seasonal MA ( <i>BTheta</i> - <code>bq</code> elements). E.g.: <code>arima.coef=c(0.6,0.7)</code> with <code>arima.p=1</code> , <code>arima.q=0</code> , <code>arima.bp=1</code> and <code>arima.bq=0</code> .
<code>arima.coefType</code>	vector defining ARMA coefficients estimation procedure. Possible procedures are: "Undefined" - no use of user-defined input (i.e. coefficients are estimated), "Fixed" - fixes the coefficients at the value provided by the user, "Initial" - the value defined by the user is used as initial condition. For orders for which the coefficients shall not be defined, the <code>arima.coef</code> can be set to NA or 0 or the <code>arima.coefType</code> can be set to "Undefined". E.g.: <code>arima.coef = c(-0.8,-0.6,NA)</code> , <code>arima.coefType = c("Fixed","Fixed","Undefined")</code> .
<code>fcst.horizon</code>	numeric, forecasts horizon. Length of the forecasts generated by the RegARIMA model in periods (positive values) or years (negative values). By default the program generates two years forecasts ( <code>fcst.horizon</code> set to -2).
<code>object</code>	deprecated argument.

## Details

The available predefined 'JDemetra+' model specifications are described in the table below.

Identifier	Log/level detection	Outliers detection	Calendar effects	ARIMA
RG0	NA	NA	NA	Airline(+mean)
RG1	automatic	AO/LS/TC	NA	Airline(+mean)

RG2c	automatic	AO/LS/TC	2 td vars + Easter	Airline(+mean)
RG3	automatic	AO/LS/TC	NA	automatic
RG4c	automatic	AO/LS/TC	2 td vars + Easter	automatic
RG5c	automatic	AO/LS/TC	7 td vars + Easter	automatic

**Value**

A list of class `c("regarima_spec", "X13")` with the below components. Each component refers to different part of the RegARIMA model specification, mirroring the arguments of the function (for details see arguments description). Each of the lowest-level component (except span, pre-specified outliers, user-defined variables and pre-specified ARMA coefficients) is structured within a data frame with columns denoting different variables of the model specification and rows referring to: first row - base specification, as provided within the argument `spec`; second row - user modifications as specified by the remaining arguments of the function (e.g.: `arma.d`); and third row - final model specification, values that will be used in the function `regarima`. The final specification (third row) shall include user modifications (row two) unless they were wrongly specified. The pre-specified outliers, user-defined variables and pre-specified ARMA coefficients consist of a list with the Predefined (base model specification) and Final values.

<code>estimate</code>	data frame. Variables referring to: <code>span</code> - time span for the model estimation, <code>tolerance</code> - argument <code>estimate.tol</code> . The final values can be also accessed with the function <code>s_estimate</code> .
<code>transform</code>	data frame. Variables referring to: <code>tfunction</code> - argument <code>transform.function</code> , <code>adjust</code> - argument <code>transform.adjust</code> , <code>aicdiff</code> - argument <code>transform.aicdiff</code> . The final values can be also accessed with the function <code>s_transform</code> .
<code>regression</code>	list including the information on the user-defined variables ( <code>usrdef</code> ), <code>trading.days</code> effect and easter effect. The user-defined part includes: <code>specification</code> - data frame with the information if pre-specified outliers ( <code>outlier</code> ) and user-defined variables ( <code>variables</code> ) are included in the model and if fixed coefficients are used ( <code>outlier.coef</code> and <code>variables.coef</code> ). The final values can be also accessed with the function <code>s_usrdef</code> ; <code>outliers</code> - matrixes with the outliers (Predefined and Final). The final outliers can be also accessed with the function <code>s_preOut</code> ; and <code>variables</code> - list with the Predefined and Final user-defined variables ( <code>series</code> ) and its description ( <code>description</code> ) including the information on the variable type and values of fixed coefficients. The final user-defined variables can be also accessed with the function <code>s_preVar</code> . Within the data frame <code>trading.days</code> variables refer to: <code>option</code> - argument <code>tradingdays.option</code> , <code>autoadjust</code> - argument <code>tradingdays.autoadjust</code> , <code>leapyear</code> - argument <code>tradingdays.leapyear</code> , <code>stocktd</code> - argument <code>tradingdays.stocktd</code> , <code>test</code> - argument <code>tradingdays.test</code> . The final <code>trading.days</code> values can be also accessed with the function <code>s_td</code> . Within the data frame easter variables refer to: <code>enabled</code> - argument <code>easter.enabled</code> , <code>julian</code> - argument <code>easter.julian</code> , <code>duration</code> - argument <code>easter.duration</code> , <code>test</code> - argument <code>easter.test</code> . The final easter values can be also accessed with the function <code>s_easter</code> .
<code>outliers</code>	data frame. Variables referring to: <code>enabled</code> - argument <code>outlier.enabled</code> , <code>span</code> - time span for the outliers' detection, <code>ao</code> - argument <code>outlier.ao</code> , <code>tc</code> - argument <code>outlier.tc</code> , <code>ls</code> - argument <code>outlier.ls</code> , <code>so</code> - argument <code>outlier.so</code> , <code>usedefcv</code>

save_spec	<i>Saving and loading a model specification, SA and pre-adjustment in X13 and TRAMO-SEATS</i>
-----------	---

---

### Description

save\_spec saves a SA or RegARIMA model specification. load\_spec loads the previously saved model specification.

### Usage

```
save_spec(object, file = file.path(tempdir(), "spec.RData"))
```

```
load_spec(file = "spec.RData")
```

**Arguments**

**object** object of one of the classes: `c("SA_spec", "X13")`, `c("SA_spec", "TRAMO_SEATS")`, `c("SA", "X13")`, `c("SA", "TRAMO_SEATS")`, `c("regarima_spec", "X13")`, `c("regarima_spec", "TRAMO_SEATS")`, `c("regarima", "X13")`, `c("regarima", "TRAMO_SEATS")`.

**file** (path and) name of the file where the model specification will be saved (have been saved).

**Details**

`save_spec` saves the final model specification of a `"SA_spec"`, `"SA"`, `"regarima_spec"` or `"regarima"` class object. `load_spec` loads the previously saved model specification. It creates a `c("SA_spec", "X13")`, `c("SA_spec", "TRAMO_SEATS")`, `c("regarima_spec", "X13")` or `c("regarima_spec", "TRAMO_SEATS")` class object, in line with the class of the previously saved model specification.

**Value**

`load_spec` returns an object of class `"SA_spec"` or `"regarima_spec"`.

**References**

save_workspace	<i>Save a workspace</i>
----------------	-------------------------

---

## Description

Functions save a workspace object into a 'JDemetra+' workspace.

## Usage

```
save_workspace(workspace, file)
```

## Arguments

workspace	a workspace object to export
file	the path to the export 'JDemetra+' workspace (.xml file). By default a dialog box opens.

**Value**

A boolean indicating whether the export has succeed.

**See Also**

[load\\_workspace](#)

**Examples**

```
dir <- tempdir()
# Create and export a empty 'JDemetra+' workspace
wk <- new_workspace()
new_multiprocessing(wk, "sa1")
save_workspace(wk, file.path(dir, "workspace.xml"))
```

---

specification	<i>Access model specification, SA and pre-adjustment in X13 and TRAMO-SEATS</i>
---------------	---

---

**Description**

Below functions access different parts of the final model specification as included in the "SA", "regarima", "SA\_spec" and "regarima\_spec" S3 class objects.

**Usage**

```
s_estimate(object = NA)
s_transform(object = NA)
s_usrdef(object = NA)
s_preOut(object = NA)
s_preVar(object = NA)
s_td(object = NA)
s_easter(object = NA)
s_out(object = NA)
s_arima(object = NA)
s_arimaCoef(object = NA)
```

```
s_fcst(object = NA)
```

```
s_span(object = NA)
```

```
s_x11(object = NA)
```

```
s_seats(object = NA)
```

### Arguments

**object** object of one of the classes: `c("SA", "X13")`, `c("SA", "TRAMO_SEATS")`, `c("SA_spec", "X13")`, `c("SA_spec", "TRAMO_SEATS")`, `c("regarima", "X13")`, `c("regarima", "TRAMO_SEATS")`, `c("regarima_spec", "X13")`, `c("regarima_spec", "TRAMO_SEATS")`.

### Value

- `s_estimate` returns a data.frame with the *estimate* variables
- `s_transform` returns a data.frame with the *transform* variables
- `s_usrdef` returns a data.frame with the *user-defined regressors* (outliers and variables) model specification, indicating if those variables are included in the model and if coefficients are pre-specified
- `s_preOut` returns a data.frame with the *pre-specified outliers*
- `s_preVar` returns a list with the information on the user-defined variables, including: `series` - the time series and `description` - data.frame with the variable type and coefficients
- `s_td` returns a data.frame with the *trading.days* variables
- `s_easter` returns a data.frame with the *easter* variables
- `s_out` returns a data.frame with the *outliers* detection variables
- `s_arima` returns a data.frame with the *arima* variables
- `s_arimaCoef` returns a data.frame with the user-specified ARMA coefficients
- `s_fcst` returns a data.frame with the forecast horizon
- `s_span` returns a data.frame with the *span* variables
- `s_x11` returns a data.frame with the *x11* variables
- `s_seats` returns a data.frame with the *seats* variables

tramoseats

*Seasonal Adjustment with TRAMO-SEATS*

---

## Description

Function to estimate the seasonally adjusted series (sa) with the TRAMO-SEATS method. This is achieved by decomposing the time series (y) into the: trend-cycle (t), seasonal component (s) and irregular component (i). The final seasonally adjusted series shall be free of seasonal and calendar-related movements. `tramoseats` returns a preformatted result while `jtramoseats` returns the Java objects of the seasonal adjustment.

## Usage

```

jtramoseats(series, spec = c("RSAfull", "RSA0", "RSA1", "RSA2", "RSA3",
  "RSA4", "RSA5"), userdefined = NULL)

tramoseats(series, spec = c("RSAfull", "RSA0", "RSA1", "RSA2", "RSA3",
  "RSA4", "RSA5"), userdefined = NULL)

```

## Arguments

<code>series</code>	a univariate time series
<code>spec</code>	model specification TRAMO-SEATS. It can be a character of the predefined TRAMO-SEATS 'JDemetra+' model specification (see <i>Details</i> ), or an object of class <code>c("SA_spec", "TRAMO_SEATS")</code> . The default is "RSAfull".
<code>userdefined</code>	vector with characters for additional output variables (see <a href="#">user_defined_variables</a> ).

## Details

The first step of the seasonal adjustment consist of pre-adjusting the time series by removing from it the deterministic effects by means of a regression model with ARIMA noise (RegARIMA, see: [regarima](#)). In the second part, the pre-adjusted series is decomposed into the following components: trend-cycle (t), seasonal component (s) and irregular component (i). The decomposition can be: additive ( $y = t + s + i$ ) or multiplicative ( $y = t * s * i$ ). The final seasonally adjusted series (sa) shall be free of seasonal and calendar-related movements.

In the TRAMO-SEATS method, the second step - SEATS ("Signal Extraction in ARIMA Time Series") - performs an ARIMA-based decomposition of an observed time series into unobserved components. More information on the method can be found on the Bank of Spain website (<https://www.bde.es>).

As regards the available predefined 'JDemetra+' TRAMO-SEATS model specifications, they are described in the table below.

Identifier	Log/level detection	Outliers detection	Calendar effects	ARIMA
RSA0	NA	NA	NA	Airline(+mean)
RSA1	automatic	AO/LS/TC	NA	Airline(+mean)
RSA2	automatic	AO/LS/TC	2 td vars + Easter	Airline(+mean)
RSA3	automatic	AO/LS/TC	NA	automatic
RSA4	automatic	AO/LS/TC	2 td vars + Easter	automatic
RSA5	automatic	AO/LS/TC	7 td vars + Easter	automatic
RSAfull	automatic	AO/LS/TC	automatic	automatic

## Value

`jtramoseats` returns a `jSA` object. It contains the Java objects of the result of the seasonal adjustment without any formatting. Therefore the computation is faster than with `tramoseats`. The results can the seasonal adjustment can be extract by `get_indicators`.

`tramoseats` returns an object of class `c("SA", "TRAMO_SEATS")`, a list containing the following components:

`regarima` object of class `c("regarima", "TRAMO_SEATS")`. See *Value* of the function [regarima](#).

`decomposition` object of class `"decomposition_SEATS"`, five elements list:

- `specification` list with the SEATS algorithm specification. See also function [tramoseats\\_spec](#)
- `mode` decomposition mode
- `model` list with the SEATS models: `model`, `sa`, `trend`, `seasonal`, `transitory`, `irregular`. Each of them is a matrix with the estimated coefficients.
- `linearized` time series matrix (`mts`) with the stochastic series decomposition (input series `y_lin`, seasonally adjusted `sa_lin`, trend `t_lin`, seasonal `s_lin`, irregular `i_lin`)
- `components` time series matrix (`mts`) with the decomposition components (input series `y_cmp`, seasonally adjusted `sa_cmp`, trend `t_cmp`, seasonal `s_cmp`, irregular `i_cmp`)

```

easter.type = "Standard",
autmdl.enabled = FALSE, arima.mu = TRUE,
usrdef.varEnabled = TRUE, usrdef.var = var)

    "decomposition.sa_lin_e"))

mysa2
plot(mysa2)
plot(mysa2$regarima)
plot(mysa2$decomposition)

```

---

tramoseats\_spec

*TRAMO-SEATS model specification, SA/TRAMO-SEATS*

---

## Description

Function to create (and/or modify) a c("SA\_spec", "TRAMO\_SEATS") class object with the SA model specification for the TRAMO-SEATS method. It can be done from a pre-defined 'JDemetra+' model specification (a character), a previous specification (c("SA\_spec", "TRAMO\_SEATS") object) or a seasonal adjustment model (c("SA", "TRAMO\_SEATS") object).

## Usage

```

tramoseats_spec(spec = c("RSAfull", "RSA0", "RSA1", "RSA2", "RSA3",
  "RSA4", "RSA5"), preliminary.check = NA,

seats.maBoundary = NA_integer_, seats.method = c(NA, "Burman",
"KalmanSmoother", "McElroyMatrix"), object)

```

## Arguments

- spec** model specification X13. It can be a character of predefined TRAMO-SEATS 'JDemetra+' model specification (see *Details*), an object of class `c("SA_spec", "TRAMO_SEATS")` or an object of class `c("SA", "TRAMO_SEATS")`. The default is "RSAfull".
- The time span of the series to be used for the estimation of the RegArima model coefficients (default from 1900-01-01 to 2020-12-31) is controlled by the following six variables: `estimate.from`, `estimate.to`, `estimate.first`, `estimate.last`, `estimate.exclFirst` and `estimate.exclLast`; where `estimate.from` and `estimate.to` have priority over remaining span control variables, `estimate.last` and `estimate.first` have priority over `estimate.exclFirst` and `estimate.exclLast`, and `estimate.last` has priority over `estimate.first`.
- preliminary.check** boolean to check the quality of the input series and exclude highly problematic ones: e.g. these with a number of identical observations and/or missing values above pre-specified threshold values.
- estimate.from** character in format "YYYY-MM-DD" indicating the start of the time span (e.g. "1900-01-01"). Can be combined with `estimate.to`.
- estimate.to** character in format "YYYY-MM-DD" indicating the end of the time span (e.g. "2020-12-31"). Can be combined with `estimate.from`.
- estimate.first** numeric specifying the number of periods considered at the beginning of the series.
- estimate.last** numeric specifying the number of periods considered at the end of the series.
- estimate.exclFirst** numeric specifying the number of periods excluded at the beginning of the series. Can be combined with `estimate.exclLast`.
- estimate.exclLast** numeric specifying the number of periods excluded at the end of the series. Can be combined with `estimate.exclFirst`.

<code>estimate.tol</code>	numeric, convergence tolerance. The absolute changes in the log-likelihood function are compared to this value to check for the convergence of the estimation iterations.
<code>estimate.eml</code>	logicals, exact maximum likelihood estimation. If TRUE the program performs an exact maximum likelihood estimation. If FASLE the Unconditional Least Squares method is used.
<code>estimate.urfinal</code>	numeric, final unit root limit. The threshold value for the final unit root test for identification of differencing orders. If the magnitude of an AR root for the final model is less than this number, a unit root is assumed, the order of the AR polynomial is reduced by one, and the appropriate order of the differencing (non-seasonal, seasonal) is increased.
<code>transform.function</code>	transformation of the input series: "None" - no transformation of the series; "Log" - takes the log of the series; "Auto" - the program tests for the log-level specification.
<code>transform.fct</code>	numeric controlling the bias in the log/level pre-test: <code>transform.fct &gt; 1</code> favours levels, <code>transform.fct &lt; 1</code> favours logs. Considered only when <code>transform.function</code> is set to "Auto". Control variables for the pre-specified outliers. The pre-specified outliers are used in the model only if they are enabled ( <code>usrdef.outliersEnabled=TRUE</code> ) and the outliers' type ( <code>usrdef.outliersType</code> ) and date ( <code>usrdef.outliersDate</code> ) are provided.
<code>usrdef.outliersEnabled</code>	logicals. If TRUE the program uses the pre-specified outliers.
<code>usrdef.outliersType</code>	vector defining the outliers' type. Possible types are: ("A0") - additive, ("LS") - level shift, ("TC") - transitory change, ("SO") - seasonal outlier. E.g.: <code>usrdef.outliersType =c("A0",</code>
<code>usrdef.outliersDate</code>	vector defining the outliers' date. The dates should be characters in format "YYYY-MM-DD". E.g.: <code>usrdef.outliersDate=c("2009-10-01", "2005-02-01", "2003-04-01")</code> .
<code>usrdef.outliersCoef</code>	vector providing fixed coefficients for the outliers. The coefficients can't be fixed if <code>transform.function</code> is set to "Auto" - the series transformation need to be pre-defined. E.g.: <code>usrdef.outliersCoef=c(200, 170, 20)</code> . Control variables for the user-defined variables:
<code>usrdef.varEnabled</code>	logicals. If TRUE the program uses the user-defined variables.
<code>usrdef.var</code>	time series (ts) or matrix of time series (mts) with the user-defined variables.
<code>usrdef.varType</code>	vector of character(s) defining the user-defined variables component type. Possible types are: "Undefined", "Series", "Trend", "Seasonal", "SeasonallyAdjusted", "Irregular". The type "Calendar" has to be used with <code>tradingdays.option = "UserDefined"</code> to use user-defined calendar regressors. If not specified, the program will assign the "Undefined" type.
<code>usrdef.varCoef</code>	vector providing fixed coefficients for the user-defined variables. The coefficients can't be fixed if <code>transform.function</code> is set to "Auto" - the series transformation need to be pre-defined.

- `tradingdays.mauto` defines whether the calendar effects should be added to the model manually ("Unused") or automatically. In the automatic selection, the choice of the number of calendar variables can be based on the F-Test ("FTest") or the Wald Test ("WaldTest"); the model with higher F value is chosen, provided that it is higher than `tradingdays.pftd`.
- `tradingdays.pftd` numeric. P-value applied in the test specified by the automatic parameter (`tradingdays.mauto`) to assess the significance of the pre-tested calendar effects variables and whether they should be included in the RegArima model.  
Control variables for the manual selection of calendar effects variables (`tradingdays.mauto` is set to "Unused"):
- `tradingdays.option` defines the type of the trading days regression variables: "TradingDays" - six day-of-the-week regression variables; "WorkingDays" - one working/non-working day contrast variable; "None" - no correction for trading days and working days effects; "UserDefined" - user-defined trading days regressors (regressors have to be defined by the `usrdef.var` argument with `usrdef.varType` set to "Calendar" and `usrdef.varEnabled = TRUE`). "None" has also to be chosen for the "day-of-week effects" correction (`tradingdays.stocktd` to be modified accordingly).
- `tradingdays.leapyear` logicals. Specifies if the leap-year correction should be included. If TRUE the model includes the leap-year effect.
- `tradingdays.stocktd` numeric indicating the day of the month when inventories and other stock are reported (to denote the last day of the month set the variable to 31). Modifications of this variable are taken into account only when `tradingdays.option` is set to "None".
- `tradingdays.test` defines the pre-tests of the trading day effects: "None" - calendar variables are used in the model without pre-testing; "Separate\_T" - a t-test is applied to each trading day variable separately and the trading day variables are included in the RegArima model if at least one t-statistic is greater than 2.6 or if two t-statistics are greater than 2.0 (in absolute terms); "Joint\_F" - a joint F-test of significance of all the trading day variables. The trading day effect is significant if the F statistic is greater than 0.95.
- `easter.type` specifies the presence and the length of the Easter effect: "Unused" - Easter effect is not considered; "Standard" - influences the period of n days strictly before Easter Sunday; "IncludeEaster" - influences the entire period (n) up to and including Easter Sunday; "IncludeEasterMonday" - influences the entire period (n) up to and including Easter Monday.
- `easter.julian` logicals. If TRUE the program uses the Julian Easter (expressed in Gregorian calendar).
- `easter.duration` numeric indicating the duration of the Easter effect (length in days, between 1 and 15).

<code>easter.test</code>	logicals. If TRUE the program performs a t-test for the significance of the Easter effect. The Easter effect is considered as significant if the modulus of t-statistic is greater than 1.96.
<code>outlier.enabled</code>	logicals. If TRUE the automatic detection of outliers is enabled in the defined time span. The time span of the series to be searched for outliers (default from 1900-01-01 to 2020-12-31) is controlled by the following six variables: <code>outlier.from</code> , <code>outlier.to</code> , <code>outlier.first</code> and <code>outlier.exclLast</code> ; where <code>outlier.from</code> and <code>outlier.to</code> have priority over remaining span control variables, <code>outlier.last</code> and <code>outlier.first</code> have priority over <code>outlier.exclFirst</code> and <code>outlier.exclLast</code> , and <code>outlier.last</code> has priority over <code>outlier.first</code> .
<code>outlier.from</code>	character in format "YYYY-MM-DD" indicating the start of the time span (e.g. "1900-01-01"). Can be combined with <code>outlier.to</code> .
<code>outlier.to</code>	character in format "YYYY-MM-DD" indicating the end of the time span (e.g. "2020-12-31"). Can be combined with <code>outlier.from</code> .
<code>outlier.first</code>	numeric specifying the number of periods considered at the beginning of the series.
<code>outlier.last</code>	numeric specifying the number of periods considered at the end of the series.
<code>outlier.exclFirst</code>	numeric specifying the number of periods excluded at the beginning of the series. Can be combined with <code>outlier.exclLast</code> .
<code>outlier.exclLast</code>	numeric specifying the number of periods excluded at the end of the series. Can be combined with <code>outlier.exclFirst</code> .
<code>outlier.ao</code>	logicals. If TRUE the automatic detection of additive outliers is enabled ( <code>outlier.enabled</code> must be also set to TRUE).
<code>outlier.tc</code>	logicals. If TRUE the automatic detection of transitory changes is enabled ( <code>outlier.enabled</code> must be also set to TRUE).
<code>outlier.ls</code>	logicals. If TRUE the automatic detection of level shifts is enabled ( <code>outlier.enabled</code> must be also set to TRUE).
<code>outlier.so</code>	logicals. If TRUE the automatic detection of seasonal outliers is enabled ( <code>outlier.enabled</code> must be also set to TRUE).
<code>outlier.usedefcv</code>	logicals. If TRUE the critical value for the outliers' detection procedure is automatically determined by the number of observations in the outlier detection time span. If FALSE the procedure uses the inputted critical value ( <code>outlier.cv</code> ).
<code>outlier.cv</code>	numeric. Inputted critical value for the outliers' detection procedure. The modification of this variable is taken in to account only when <code>outlier.usedefcv</code> is set to FALSE.
<code>outlier.eml</code>	logicals, exact likelihood estimation method. Controls the method applied for a parameter estimation in the intermediate steps of the automatic detection and correction of outliers. If TRUE an exact likelihood estimation method is used, when FALSE the fast Hannan-Rissanen method is used.
<code>outlier.tcrate</code>	numeric. The rate of decay for the transitory change outlier.

- `automdl.enabled`  
 logicals. If TRUE the automatic modelling of the ARIMA model is enabled. If FALSE the parameters of the ARIMA model can be specified.  
 Control variables for the automatic modelling of the ARIMA model (`automdl.enabled` is set to TRUE):
- `automdl.acceptdefault`  
 logicals. If TRUE the default model (ARIMA(0,1,1)(0,1,1)) may be chosen in the first step of the automatic model identification. If the Ljung-Box Q statistics for the residuals is acceptable, the default model is accepted and no further attempt will be made to identify any other.
- `automdl.cancel` numeric, cancelation limit. If the difference in moduli of an AR and an MA roots (when estimating ARIMA(1,0,1)(1,0,1) models in the second step of the automatic identification of the differencing orders) is smaller than cancelation limit, the two roots are assumed equal and cancel out.
- `automdl.ub1` numeric, first unit root limit. It is the threshold value for the initial unit root test in the automatic differencing procedure. When one of the roots in the estimation of the ARIMA(2,0,0)(1,0,0) plus mean model, performed in the first step of the automatic model identification procedure, is larger than first unit root limit in modulus, it is set equal to unity.
- `automdl.ub2` numeric, second unit root limit. When one of the roots in the estimation of the ARIMA(1,0,1)(1,0,1) plus mean model, which is performed in the second step of the automatic model identification procedure, is larger than second unit root limit in modulus, it is checked if there is a common factor in the corresponding AR and MA polynomials of the ARMA model that can be cancelled (see `automdl.cancel`). If there is no cancellation, the AR root is set equal to unity (i.e. the differencing order changes).
- `automdl.arma limit`  
 numeric, arma limit. It is the threshold value for t-statistics of ARMA coefficients and constant term used for the final test of model parsimony. If the highest order ARMA coefficient has a t-value less than this value in magnitude, the order of the model is reduced. Also if the constant term has a t-value less than arma limit in magnitude, it is removed from the set of regressors.
- `automdl.reducecv`  
 numeric, ReduceCV. The percentage by which the outlier's critical value will be reduced when an identified model is found to have a Ljung-Box statistic with an unacceptable confidence coefficient. The parameter should be between 0 and 1, and will only be active when automatic outlier identification is enabled. The reduced critical value will be set to  $(1 - \text{ReduceCV}) \times \text{CV}$ , where CV is the original critical value.
- `automdl.ljungbox limit`  
 numeric, Ljung Box limit. Acceptance criterion for the confidence intervals of the Ljung-Box Q statistic. If the LjungBox Q statistics for the residuals of a final model is greater than Ljung Box limit, the model is rejected, the outlier critical value is reduced, and model and outlier identification (if specified) is redone with a reduced value.
- `automdl.compare`  
 logicals. If TRUE the program compares the model identified by the automatic procedure to the default model (ARIMA(0,1,1)(0,1,1)) and the model with the

best fit is selected. Criteria considered are residual diagnostics, the model structure and the number of outliers.

Control variables for the non-automatic modelling of the ARIMA model (`automdl.enabled` is set to FALSE):

<code>arima.mu</code>	logicals. If TRUE, the mean is considered as part of the ARIMA model.
<code>arima.p</code>	numeric. The order of the non-seasonal autoregressive (AR) polynomial.
<code>arima.d</code>	numeric. Regular differencing order.
<code>arima.q</code>	numeric. The order of the non-seasonal moving average (MA) polynomial.
<code>arima.bp</code>	numeric. The order of the seasonal autoregressive (AR) polynomial.
<code>arima.bd</code>	numeric. Seasonal differencing order.
<code>arima.bq</code>	numeric. The order of the seasonal moving average (MA) polynomial.
<code>arima.coefEnabled</code>	logicals. If TRUE the program uses the user-defined ARMA coefficients.
<code>arima.coef</code>	vector providing the coefficients for the regular and seasonal AR and MA polynomials. The length of the vector must equal the sum of the regular and seasonal AR and MA orders. The coefficients shall be provided in the order: regular AR ( <i>Phi</i> - p elements), regular MA ( <i>Theta</i> - q elements), seasonal AR ( <i>BPhi</i> - bp elements) and seasonal MA ( <i>BTheta</i> - bq elements). E.g.: <code>arima.coef=c(0.6,0.7)</code> with <code>arima.p=1</code> , <code>arima.q=0</code> , <code>arima.bp=1</code> and <code>arima.bq=0</code> .
<code>arima.coefType</code>	vector defining ARMA coefficients estimation procedure. Possible procedures are: "Undefined" - no use of user-defined input (i.e. coefficients are estimated), "Fixed" - fixes the coefficients at the value provided by the user, "Initial" - the value defined by the user is used as initial condition. For orders for which the coefficients shall not be defined, the <code>arima.coef</code> can be set to NA or 0 or the <code>arima.coefType</code> can be set to "Undefined". E.g.: <code>arima.coef = c(-0.8,-0.6,NA)</code> , <code>arima.coefType = c("Fixed","Fixed","Undefined")</code> .
<code>fcst.horizon</code>	numeric, forecasts horizon. Length of the forecasts generated by the RegARIMA model in periods (positive values) or years (negative values). By default the program generates two years forecasts ( <code>fcst.horizon</code> set to -2).
<code>seats.approx</code>	character, approximation mode. When the ARIMA model estimated by TRAMO does not accept an admissible decomposition, SEATS: "None" - performs an approximation; "Legacy" - replaces the model with a decomposable one; "Noisy" - estimates a new model by adding a white noise to the non-admissible model estimated by TRAMO.
<code>seats.trendBoundary</code>	numeric, trend boundary. The boundary from which an AR root is integrated in the trend component. If the modulus of the inverse real root is greater than Trend boundary, the AR root is integrated in the trend component. Below this value the root is integrated in the transitory component.

seats.seasdBoundary	numeric, seasonal boundary. Boundary from which a negative AR root is integrated in the seasonal component.
seats.seasdBoundary1	numeric, seasonal boundary (unique). Boundary from which a negative AR root is integrated in the seasonal component when the root is the unique seasonal root.
seats.seasTol	numeric, seasonal tolerance. The tolerance (measured in degrees) to allocate the AR non-real roots to the seasonal component (if the modulus of the inverse complex AR root is greater than Trend boundary and the frequency of this root differs from one of the seasonal frequencies by less than Seasonal tolerance) or the transitory component (otherwise).
seats.maBoundary	numeric, MA unit root boundary. When the modulus of an estimated MA root falls in the range (xl, 1), it is set to xl.
seats.method	character, estimation method of the unobserved components. The choice can be made from: "Burman" (default, may result in a significant underestimation of the standard deviations of the components as it may become numerically unstable when some roots of the MA polynomial are near 1); "KalmanSmoother" (it is not disturbed by the (quasi-) unit roots in MA); "McElroyMatrix" (has the same stability issues as the Burman's algorithm).
object	deprecated argument.

## Details

The available predefined 'JDemetra+' model specifications are described in the table below.

Identifier	Log/level detection	Outliers detection	Calendar effects	ARIMA
RSA0	NA	NA	NA	Airline(+mean)
RSA1	automatic	AO/LS/TC	NA	Airline(+mean)
RSA2	automatic	AO/LS/TC	2 td vars + Easter	Airline(+mean)
RSA3	automatic	AO/LS/TC	NA	automatic
RSA4	automatic	AO/LS/TC	2 td vars + Easter	automatic
RSA5	automatic	AO/LS/TC	7 td vars + Easter	automatic
RSAfull	automatic	AO/LS/TC	automatic	automatic

## Value

A two-elements list of class `c("SA_spec", "TRAMO_SEATS")`: (1) object of class `c("regarima_spec", "TRAMO_SEATS")` with the RegARIMA model specification, (2) object of class `c("seats_spec", "data.frame")` with the SEATS algorithm specification. Each component refers to different part of the SA model specification, mirroring the arguments of the function (for details see arguments description). Each of the lowest-level component (except span, pre-specified outliers, user-defined variables and pre-specified ARMA coefficients) is structured within a data frame with columns denoting different variables of the model specification and rows referring to: first row - base specification, as provided within the argument spec; second row - user modifications as specified by the remaining arguments of the function (e.g.: `arma.d`); and third row - final model specification. The final specification (third row) shall include user modifications (row two) unless they were wrongly specified. The

---

user\_defined\_variables

*Get the names of the user-defined variables*

---

## Description

Function to get the names of the additional output variables that can be defined in [x13](#) and [tramoseats](#) with the parameter `userdefined`.

## Usage

```
user_defined_variables(sa_object = c("X13-ARIMA", "TRAMO-SEATS"))
```

**Arguments**

`sa_object` a character: "X13-ARIMA" to get the additional output variables available for the X13-ARIMA method and "TRAMO-SEATS" for the TRAMO-SEATS method.

**Examples**

```
user_defined_variables("X13-ARIMA")
user_defined_variables("TRAMO-SEATS")
```

x13

*Seasonal Adjustment with X-13ARIMA-SEATS***Description**

Functions to estimate the seasonally adjusted series (sa) with the X-13ARIMA-SEATS method. This is achieved by decomposing the time series (y) into the: trend-cycle (t), seasonal component (s) and irregular component (i). The final seasonally adjusted series shall be free of seasonal and calendar-related movements. x13 returns a preformatted result while jx13 returns the Java objects of the seasonal adjustment.

**Usage**

```
jx13(series, spec = c("RSA5c", "RSA0", "RSA1", "RSA2c", "RSA3", "RSA4c"),
     userdefined = NULL)
```

```
x13(series, spec = c("RSA5c", "RSA0", "RSA1", "RSA2c", "RSA3", "RSA4c"),
     userdefined = NULL)
```

**Arguments**

`series` a univariate time series

`spec` model specification X13. It can be a character of predefined X13 'JDemetra+' model specification (see *Details*), or an object of class `c("SA_spec", "X13")`. The default is "RSA5c".

`userdefined` vector with characters for additional output variables (see [user\\_defined\\_variables](#)).

**Details**

The first step of the seasonal adjustment consist of pre-adjusting the time series by removing from it the deterministic effects by means of a regression model with ARIMA noise (RegARIMA, see: [regarima](#)). In the second part, the pre-adjusted series is decomposed into the following components: trend-cycle (t), seasonal component (s) and irregular component (i). The decomposition can be: additive ( $y = t + s + i$ ), multiplicative ( $y = t * s * i$ ), log-additive ( $\log(y) = \log(t) + \log(s) + \log(i)$ ) or pseudo-additive ( $y = t * (s + i - 1)$ ). The final seasonally adjusted series (sa) shall be free of seasonal and calendar-related movements.

In the X13 method, the X11 algorithm (second step) decomposes the time series by means of linear filters. More information on the method can be found on the U.S. Census Bureau website.

As regards the available predefined 'JDemetra+' X13 model specifications, they are described in the table below.

Identifier	Log/level detection	Outliers detection	Calendar effects	ARIMA
RSA0	NA	NA	NA	Airline(+mean)
RSA1	automatic	AO/LS/TC	NA	Airline(+mean)
RSA2c	automatic	AO/LS/TC	2 td vars + Easter	Airline(+mean)
RSA3	automatic	AO/LS/TC	NA	automatic
RSA4c	automatic	AO/LS/TC	2 td vars + Easter	automatic
RSA5c	automatic	AO/LS/TC	7 td vars + Easter	automatic

## Value

`jx13` returns a `jSA` object. It contains the Java objects of the result of the seasonal adjustment without any formatting. Therefore the computation is faster than with `x13`. The results can the seasonal adjustment can be extract by `get_indicators`.

`x13` returns an object of class `c("SA", "X13")`, a list containing the following components:

<code>regarima</code>	object of class <code>c("regarima", "X13")</code> . See <i>Value</i> of the function <code>regarima</code> .
<code>decomposition</code>	object of class <code>"decomposition_X11"</code> , six elements list: <ul style="list-style-type: none"> <li>• specification list with the X11 algorithm specification. See also function <code>x13_spec</code></li> <li>• mode decomposition mode</li> <li>• <code>mstats</code> matrix with the M statistics</li> <li>• <code>si_ratio</code> time series matrix (mts) with the d8 and d10 series</li> <li>• <code>s_filter</code> seasonal filters</li> <li>• <code>t_filter</code> trend filter</li> </ul>
<code>final</code>	object of class <code>c("final", "mts", "ts", "matrix")</code> . Matrix with the final results of the seasonal adjustment. It includes time series: original time series ( <code>y</code> ), forecast of the original series ( <code>y_f</code> ), trend ( <code>t</code> ), forecast of the trend ( <code>t_f</code> ), seasonally adjusted series ( <code>sa</code> ), forecast of the seasonally adjusted series ( <code>sa_f</code> ), seasonal component ( <code>s</code> ), forecast of the seasonal component ( <code>s_f</code> ), irregular component ( <code>i</code> ) and the forecast of the irregular component ( <code>i_f</code> ).
<code>diagnostics</code>	object of class <code>"diagnostics"</code> , list with three type of diagnostics tests: <ul style="list-style-type: none"> <li>• <code>variance_decomposition</code> data.frame with the tests on the relative contribution of the components to the stationary portion of the variance in the original series, after the removal of the long term trend.</li> <li>• <code>residuals_test</code> data.frame with the tests on the presence of seasonality in the residuals (includes the statistic, p-value and parameters description)</li> <li>• <code>combined_test</code> combined tests for stable seasonality in the entire series. Two elements list with: <code>tests_for_stable_seasonality</code> - data.frame with the tests (includes the statistic, p-value and parameters description) and <code>combined_seasonality_test</code> - the summary.</li> </ul>
<code>user_defined</code>	object of class <code>"user_defined"</code> . List containing the userdefined additional variables defined in the <code>userdefined</code> argument.

## Description

Function to create (and/or modify) a `c("SA_spec", "X13")` class object with the SA model specification for the X13 method. It can be done from a pre-defined 'JDemetra+' model specification (a character), a previous specification (`c("SA_spec", "X13")` object) or a seasonal adjustment model (`c("SA", "X13")` object).

**Arguments**

spec	<p>model specification X13. It can be a character of predefined X13 'JDemetra+' model specification (see <i>Details</i>), an object of class <code>c("SA_spec", "X13")</code> or an object of class <code>c("SA", "X13")</code>. The default is "RSA5c".</p> <p>The time span of the series to be used for the estimation of the RegArima model coefficients (default from 1900-01-01 to 2020-12-31) is controlled by the following six variables: <code>estimate.from</code>, <code>estimate.to</code>, <code>estimate.first</code>, <code>estimate.last</code>, <code>estimate.exclFirst</code> and <code>estimate.exclLast</code>; where <code>estimate.from</code> and <code>estimate.to</code> have priority over remaining span control variables, <code>estimate.last</code> and <code>estimate.first</code> have priority over <code>estimate.exclFirst</code> and <code>estimate.exclLast</code>, and <code>estimate.last</code> has priority over <code>estimate.first</code>.</p>
preliminary.check	<p>boolean to check the quality of the input series and exclude highly problematic ones: e.g. these with a number of identical observations and/or missing values above pre-specified threshold values.</p>
estimate.from	<p>character in format "YYYY-MM-DD" indicating the start of the time span (e.g. "1900-01-01"). Can be combined with <code>estimate.to</code>.</p>
estimate.to	<p>character in format "YYYY-MM-DD" indicating the end of the time span (e.g. "2020-12-31"). Can be combined with <code>estimate.from</code>.</p>
estimate.first	<p>numeric specifying the number of periods considered at the beginning of the series.</p>
estimate.last	<p>numeric specifying the number of periods considered at the end of the series.</p>
estimate.exclFirst	<p>numeric specifying the number of periods excluded at the beginning of the series. Can be combined with <code>estimate.exclLast</code>.</p>
estimate.exclLast	<p>numeric specifying the number of periods excluded at the end of the series. Can be combined with <code>estimate.exclFirst</code>.</p>
estimate.tol	<p>numeric, convergence tolerance. The absolute changes in the log-likelihood function are compared to this value to check for the convergence of the estimation iterations.</p>
transform.function	<p>transformation of the input series: "None" - no transformation of the series; "Log" - takes the log of the series; "Auto" - the program tests for the log-level specification.</p>
transform.adjust	<p>pre-adjustment of the input series for length of period or leap year effects: "None" - no adjustment; "LeapYear" - leap year effect; "LengthOfPeriod" - length of period. Modifications of this variable are taken into account only when <code>transform.function</code> is set to "Log".</p>
transform.aicdiff	<p>numeric defining the difference in AICC needed to accept no transformation when the automatic transformation selection is chosen (considered only when <code>transform.function</code> is set to "Auto").</p> <p>Control variables for the pre-specified outliers. The pre-specified outliers are used in the model only if they are enabled (<code>usrdef.outliersEnabled=TRUE</code>)</p>

- and the outliers' type (`usrdef.outliersType`) and date (`usrdef.outliersDate`) are provided.
- `usrdef.outliersEnabled`  
 logicals. If TRUE the program uses the pre-specified outliers.
- `usrdef.outliersType`  
 vector defining the outliers' type. Possible types are: ("A0") - additive, ("LS") - level shift, ("TC") - transitory change, ("SO") - seasonal outlier. E.g.: `usrdef.outliersType =c("A0"`
- `usrdef.outliersDate`  
 vector defining the outliers' date. The dates should be characters in format "YYYY-MM-DD". E.g.: `usrdef.outliersDate=c("2009-10-01", "2005-02-01", "2003-04-01")`.
- `usrdef.outliersCoef`  
 vector providing fixed coefficients for the outliers. The coefficients can't be fixed if `transform.function` is set to "Auto" - the series transformation need to be pre-defined. E.g.: `usrdef.outliersCoef=c(200,170,20)`.  
 Control variables for the user-defined variables:
- `usrdef.varEnabled`  
 logicals. If TRUE the program uses the user-defined variables.
- `usrdef.var`  
 time series (ts) or matrix of time series (mts) with the user-defined variables.
- `usrdef.varType`  
 vector of character(s) defining the user-defined variables component type. Possible types are: "Undefined", "Series", "Trend", "Seasonal", "SeasonallyAdjusted", "Irregular". The type "Calendar" has to be used with `tradingdays.option = "UserDefined"` to use user-defined calendar regressors. If not specified, the program will assign the "Undefined" type.
- `usrdef.varCoef`  
 vector providing fixed coefficients for the user-defined variables. The coefficients can't be fixed if `transform.function` is set to "Auto" - the series transformation need to be pre-defined.
- `tradingdays.option`  
 defines the type of the trading days regression variables: "TradingDays" - six day-of-the-week regression variables; "WorkingDays" - one working/non-working day contrast variable; "None" - no correction for trading days and working days effects; "UserDefined" - user-defined trading days regressors (regressors have to be defined by the `usrdef.var` argument with `usrdef.varType` set to "Calendar" and `usrdef.varEnabled = TRUE`). "None" has also to be chosen for the "day-of-week effects" correction (`tradingdays.stocktd` to be modified accordingly).
- `tradingdays.autoadjust`  
 logicals. If TRUE the program corrects automatically for the leap year effect. Modifications of this variable are taken into account only when `transform.function` is set to "Auto".
- `tradingdays.leapyear`  
 option for including the leap-year effect in the model: "LeapYear" - leap year effect; "LengthOfPeriod" - length of period, "None" - no effect included. The leap-year effect can be pre-specified in the model only if the input series was not pre-adjusted (`transform.adjust` set to "None") and the automatic correction for the leap-year effect was not selected (`tradingdays.autoadjust` set to FALSE).

<code>tradingdays.stocktd</code>	numeric indicating the day of the month when inventories and other stock are reported (to denote the last day of the month set the variable to 31). Modifications of this variable are taken into account only when <code>tradingdays.option</code> is set to "None".
<code>tradingdays.test</code>	defines the pre-tests for the significance of the trading day regression variables based on the AICC statistics: "Add" - the trading day variables are not included in the initial regression model but can be added to the RegARIMA model after the test; "Remove" - the trading day variables belong to the initial regression model but can be removed from the RegARIMA model after the test; "None" - the trading day variables are not pre-tested and are included in the model.
<code>easter.enabled</code>	logicals. If TRUE the program considers the Easter effect in the model.
<code>easter.julian</code>	logicals. If TRUE the program uses the Julian Easter (expressed in Gregorian calendar).
<code>easter.duration</code>	numeric indicating the duration of the Easter effect (length in days, between 1 and 20).
<code>easter.test</code>	defines the pre-tests for the significance of the Easter effect based on the t-statistic (Easter effect is considered as significant if the t-statistic is greater than 1.96): "Add" - the Easter effect variable is not included in the initial regression model but can be added to the RegARIMA model after the test; "Remove" - the Easter effect variable belong to the initial regression model but can be removed from the RegARIMA model after the test; "None" - the Easter effect variable is not pre-tested and is included in the model.
<code>outlier.enabled</code>	logicals. If TRUE the automatic detection of outliers is enabled in the defined time span. The time span of the series to be searched for outliers (default from 1900-01-01 to 2020-12-31) is controlled by the following six variables: <code>outlier.from</code> , <code>outlier.to</code> , <code>outlier.first</code> and <code>outlier.exclLast</code> ; where <code>outlier.from</code> and <code>outlier.to</code> have priority over remaining span control variables, <code>outlier.last</code> and <code>outlier.first</code> have priority over <code>outlier.exclFirst</code> and <code>outlier.exclLast</code> , and <code>outlier.last</code> has priority over <code>outlier.first</code> .
<code>outlier.from</code>	character in format "YYYY-MM-DD" indicating the start of the time span (e.g. "1900-01-01"). Can be combined with <code>outlier.to</code> .
<code>outlier.to</code>	character in format "YYYY-MM-DD" indicating the end of the time span (e.g. "2020-12-31"). Can be combined with <code>outlier.from</code> .
<code>outlier.first</code>	numeric specifying the number of periods considered at the beginning of the series.
<code>outlier.last</code>	numeric specifying the number of periods considered at the end of the series.
<code>outlier.exclFirst</code>	numeric specifying the number of periods excluded at the beginning of the series. Can be combined with <code>outlier.exclLast</code> .
<code>outlier.exclLast</code>	numeric specifying the number of periods excluded at the end of the series. Can be combined with <code>outlier.exclFirst</code> .

<code>outlier.ao</code>	logicals. If TRUE the automatic detection of additive outliers is enabled ( <code>outlier.enabled</code> must be also set to TRUE).
<code>outlier.tc</code>	logicals. If TRUE the automatic detection of transitory changes is enabled ( <code>outlier.enabled</code> must be also set to TRUE).
<code>outlier.ls</code>	logicals. If TRUE the automatic detection of level shifts is enabled ( <code>outlier.enabled</code> must be also set to TRUE).
<code>outlier.so</code>	logicals. If TRUE the automatic detection of seasonal outliers is enabled ( <code>outlier.enabled</code> must be also set to TRUE).
<code>outlier.usedefcv</code>	logicals. If TRUE the critical value for the outliers' detection procedure is automatically determined by the number of observations in the outlier detection time span. If FALSE the procedure uses the inputted critical value ( <code>outlier.cv</code> ).
<code>outlier.cv</code>	numeric. Inputted critical value for the outliers' detection procedure. The modification of this variable is taken into account only when <code>outlier.usedefcv</code> is set to FALSE.
<code>outlier.method</code>	determines how the program successively adds detected outliers to the model. At present only the AddOne method is supported.
<code>outlier.tcrate</code>	numeric. The rate of decay for the transitory change outlier.
<code>automdl.enabled</code>	logicals. If TRUE the automatic modelling of the ARIMA model is enabled. If FALSE the parameters of the ARIMA model can be specified. Control variables for the automatic modelling of the ARIMA model ( <code>automdl.enabled</code> is set to TRUE):
<code>automdl.acceptdefault</code>	logicals. If TRUE the default model (ARIMA(0,1,1)(0,1,1)) may be chosen in the first step of the automatic model identification. If the Ljung-Box Q statistics for the residuals is acceptable, the default model is accepted and no further attempt will be made to identify any other.
<code>automdl.cancel</code>	numeric, cancelation limit. If the difference in moduli of an AR and an MA roots (when estimating ARIMA(1,0,1)(1,0,1) models in the second step of the automatic identification of the differencing orders) is smaller than cancelation limit, the two roots are assumed equal and cancel out.
<code>automdl.ub1</code>	numeric, first unit root limit. It is the threshold value for the initial unit root test in the automatic differencing procedure. When one of the roots in the estimation of the ARIMA(2,0,0)(1,0,0) plus mean model, performed in the first step of the automatic model identification procedure, is larger than first unit root limit in modulus, it is set equal to unity.
<code>automdl.ub2</code>	numeric, second unit root limit. When one of the roots in the estimation of the ARIMA(1,0,1)(1,0,1) plus mean model, which is performed in the second step of the automatic model identification procedure, is larger than second unit root limit in modulus, it is checked if there is a common factor in the corresponding AR and MA polynomials of the ARMA model that can be cancelled (see <code>automdl.cancel</code> ). If there is no cancellation, the AR root is set equal to unity (i.e. the differencing order changes).

<code>automdl.mixed</code>	logicals. The variable controls whether ARIMA models with non-seasonal AR and MA terms or seasonal AR and MA terms will be considered in the automatic model identification procedure. If FALSE a model with AR and MA terms in both the seasonal and non-seasonal parts of the model can be acceptable, provided there are not AR and MA terms in either the seasonal or non-seasonal.
<code>automdl.balanced</code>	logicals. If TRUE, the automatic model identification procedure will have a preference for balanced models (i.e. models for which the order of the combined AR and differencing operator is equal to the order of the combined MA operator).
<code>automdl.armalimit</code>	numeric, arma limit. It is the threshold value for t-statistics of ARMA coefficients and constant term used for the final test of model parsimony. If the highest order ARMA coefficient has a t-value less than this value in magnitude, the order of the model is reduced. Also if the constant term has a t-value less than arma limit in magnitude, it is removed from the set of regressors.
<code>automdl.reducecv</code>	numeric, ReduceCV. The percentage by which the outlier's critical value will be reduced when an identified model is found to have a Ljung-Box statistic with an unacceptable confidence coefficient. The parameter should be between 0 and 1, and will only be active when automatic outlier identification is enabled. The reduced critical value will be set to $(1 - \text{ReduceCV}) \times \text{CV}$ , where CV is the original critical value.
<code>automdl.ljungboxlimit</code>	numeric, Ljung Box limit. Acceptance criterion for the confidence intervals of the Ljung-Box Q statistic. If the LjungBox Q statistics for the residuals of a final model is greater than Ljung Box limit, the model is rejected, the outlier critical value is reduced, and model and outlier identification (if specified) is redone with a reduced value.
<code>automdl.ubfinal</code>	numeric, final unit root limit. The threshold value for the final unit root test. If the magnitude of an AR root for the final model is less than the final unit root limit, a unit root is assumed, the order of the AR polynomial is reduced by one, and the appropriate order of the differencing (non-seasonal, seasonal) is increased. The parameter value should be greater than one. Control variables for the non-automatic modelling of the ARIMA model ( <code>automdl.enabled</code> is set to FALSE):
<code>arma.mu</code>	logicals. If TRUE, the mean is considered as part of the ARIMA model.
<code>arma.p</code>	numeric. The order of the non-seasonal autoregressive (AR) polynomial.
<code>arma.d</code>	numeric. Regular differencing order.
<code>arma.q</code>	numeric. The order of the non-seasonal moving average (MA) polynomial.
<code>arma.bp</code>	numeric. The order of the seasonal autoregressive (AR) polynomial.
<code>arma.bd</code>	numeric. Seasonal differencing order.
<code>arma.bq</code>	numeric. The order of the seasonal moving average (MA) polynomial. Control variables for the user-defined ARMA coefficients. Coefficients can be defined for the regular and seasonal autoregressive (AR) polynomials and moving average (MA) polynomials. The model considers the coefficients only if the

procedure for their estimation (`arima.coefType`) is provided, and the number of provided coefficients matches the sum of (regular and seasonal) AR and MA orders (`p, q, bp, bq`).

<code>arima.coefEnabled</code>	logicals. If TRUE the program uses the user-defined ARMA coefficients.
<code>arima.coef</code>	vector providing the coefficients for the regular and seasonal AR and MA polynomials. The length of the vector must equal the sum of the regular and seasonal AR and MA orders. The coefficients shall be provided in the order: regular AR ( <i>Phi</i> - <code>p</code> elements), regular MA ( <i>Theta</i> - <code>q</code> elements), seasonal AR ( <i>BPhi</i> - <code>bp</code> elements) and seasonal MA ( <i>BTheta</i> - <code>bq</code> elements). E.g.: <code>arima.coef=c(0.6,0.7)</code> with <code>arima.p=1</code> , <code>arima.q=0</code> , <code>arima.bp=1</code> and <code>arima.bq=0</code> .
<code>arima.coefType</code>	vector defining ARMA coefficients estimation procedure. Possible procedures are: "Undefined" - no use of user-defined input (i.e. coefficients are estimated), "Fixed" - fixes the coefficients at the value provided by the user, "Initial" - the value defined by the user is used as initial condition. For orders for which the coefficients shall not be defined, the <code>arima.coef</code> can be set to NA or 0 or the <code>arima.coefType</code> can be set to "Undefined". E.g.: <code>arima.coef = c(-0.8,-0.6,NA)</code> , <code>arima.coefType = c("Fixed","Fixed","Undefined")</code> .
<code>fcst.horizon</code>	numeric, forecasts horizon. Length of the forecasts generated by the RegARIMA model in periods (positive values) or years (negative values). By default the program generates two years forecasts ( <code>fcst.horizon</code> set to -2).
<code>x11.mode</code>	character, decomposition mode. Determines the mode of the seasonal adjustment decomposition to be performed: "Undefined" - no assumption concerning the relationship between the time series components is made; "Additive" - assumes an additive relationship; "Multiplicative" - assumes a multiplicative relationship; "LogAdditive" - performs an additive decomposition of the logarithms of the series being adjusted; "PseudoAdditive" - assumes an pseudo-additive relationship. Could be changed by the program, if needed.
<code>x11.seasonalComp</code>	logicals. If TRUE the program computes a seasonal component. Otherwise, the seasonal component is not estimated and its values are all set to 0 (additive decomposition) or 1 (multiplicative decomposition).
<code>x11.lsigma</code>	numeric, lower sigma boundary for the detection of extreme values.
<code>x11.usigma</code>	numeric, upper sigma boundary for the detection of extreme values.
<code>x11.trendAuto</code>	logicals, automatic Henderson filter. If TRUE an automatic selection of the Henderson filter's length for the trend estimation is enabled.
<code>x11.trendma</code>	numeric, length of the Henderson filter. The user-defined length of the Henderson filter. The option is available when the automatic Henderson filter selection is disabled ( <code>x11.trendAuto=FALSE</code> ). Should be an odd number in the range (1, 101].
<code>x11.seasonalma</code>	vector of character(s) specifying which seasonal moving average (i.e. seasonal filter) will be used to estimate the seasonal factors for the entire series. The vector can be of length: 1 - same seasonal filters for all periods (e.g.: <code>seasonalma=c("Msr")</code> ); or period's number - a seasonal filter is defined for each period (e.g. for quarterly series: <code>seasonalma=c("S3X3","Msr","S3X3","Msr")</code> ). Possible filters are:

"Msr", "Stable", "X11Default", "S3X1", "S3X3", "S3X5", "S3X9", "S3X15".  
 "Msr" - the program chooses the final seasonal filter automatically.

x11.fcasts	numeric, RegARIMA forecast. Length of the forecasts generated by the RegARIMA model in periods (positive values) or years (negative values).
x11.bccasts	numeric, backcast. Length of the backcasts used in X11. Negative figures are translated in years of backcasts.
x11.excludeFcasts	logicals, exclude forecasts and backcasts. If TRUE forecasts and backcasts from the RegARIMA model are not used in the generation of extreme values in the seasonal adjustment routines.
object	deprecated argument.

## Details

The available predefined 'JDemetra+' model specifications are described in the table below.

Identifier	Log/level detection	Outliers detection	Calendar effects	ARIMA
RSA0	NA	NA	NA	Airline(+mean)
RSA1	automatic	AO/LS/TC	NA	Airline(+mean)
RSA2c	automatic	AO/LS/TC	2 td vars + Easter	Airline(+mean)
RSA3	automatic	AO/LS/TC	NA	automatic
RSA4c	automatic	AO/LS/TC	2 td vars + Easter	automatic
RSA5c	automatic	AO/LS/TC	7 td vars + Easter	automatic

## Value

A two-elements list of class `c("SA_spec", "X13")`: (1) object of class `c("regarima_spec", "X13")` with the RegARIMA model specification, (2) object of class `c("X11_spec", "data.frame")` with the X11 algorithm specification. Each component refers to different part of the SA model specification, mirroring the arguments of the function (for details see arguments description). Each of the lowest-level component (except span, pre-specified outliers, user-defined variables and pre-specified ARMA coefficients) is structured within a data frame with columns denoting different variables of the model specification and rows referring to: first row - base specification, as provided within the argument `spec`; second row - user modifications as specified by the remaining arguments of the function (e.g.: `arma.d`); and third row - final model specification. The final specification (third row) shall include user modifications (row two) unless they were wrongly specified. The pre-specified outliers, user-defined variables and pre-specified ARMA coefficients consist of a list with the Predefined (base model specification) and Final values.

<code>regarima</code>	object of class <code>c("regarima_spec", "x13")</code> . See <i>Value</i> of the function <a href="#">regarima_spec_x13</a>
<code>x11</code>	<code>data.frame</code> of class <code>c("X11_spec", "data.frame")</code> , containing the <i>x11</i> variables in line with the names of the arguments variables. The final values can be also accessed with the function <a href="#">s_x11</a> .
