

# An Object-Oriented Solution for Robust Factor Analysis \*

Ying-Ying Zhang  
Chongqing University

---

## Abstract

Taking advantage of the S4 class system of the programming environment R, which facilitates the creation and maintenance of reusable and modular components, an object-oriented solution for robust factor analysis is developed. The solution resides in the package **robustfa**. In the solution, new S4 classes "Fa", "FaClassic", "FaRobust", "FaCov", "SummaryFa" are created. The robust factor analysis function `FaCov()` can deal with maximum likelihood estimation, principal component analysis, and principal factor analysis methods. Consider the factor analysis methods (classical or robust), the data input (data or the scaled data), and the running matrix (covariance or correlation) all together, there are 8 combinations. We recommend classical and robust factor analysis using the correlation matrix of the scaled data as the running matrix for theoretical and computational reasons. The design of the solution follows common statistical design patterns. The application of the solution to multivariate data analysis is demonstrated on the **hbk** data and the **stock611** data which themselves are parts of the package **robustfa**.

*Keywords:* robustness, factor analysis, object-oriented solution, R, statistical design patterns.

---

## 1. Introduction

Outliers exist in virtually every data set in any application domain. In order to avoid the masking effect, robust estimators are needed. The classical estimators of multivariate location and scatter are the sample mean  $\bar{\mathbf{x}}$  and the sample covariance matrix  $\mathbf{S}$ . These estimates are optimal if the data come from a multivariate normal distribution but are extremely sensitive to the presence of even a few outliers. If outliers are present in the input data they will influence the estimates  $\bar{\mathbf{x}}$  and  $\mathbf{S}$  and subsequently worsen the performance of the classical factor analysis (Pison *et al.* 2003). Therefore it is important to consider robust alternatives to these estimators. There are several robust estimators in the literature: MCD (Rousseeuw 1985; Rousseeuw and Driessen 1999), OGK (Maronna and Zamar 2002), MVE (Rousseeuw 1985), M (Rocke 1996), S (Davies 1987; Ruppert 1992; Woodruff and Rocke 1994; Rocke 1996; He and Wang 1997; Salibian-Barrera and Yohai 2006) and Stahel-Donoho (Stahel 1981a,b; Donoho 1982; Maronna and Yohai 1995). Substituting the classical location and scatter estimates by their robust analogues is the most straightforward method for robustifying many multivariate procedures (Maronna *et al.* 2006; Todorov and Filzmoser 2009), which is our choice for robustifying the factor analysis procedure.

\*The research was supported by Natural Science Foundation Project of CQ CSTC CSTC2011BB0058.

Taking advantage of the new S4 class system (Chambers 1998) of R (R Development Core Team 2009) which facilitate the creation of reusable and modular components, an object-oriented solution for robust factor analysis is implemented. The application of the solution to multivariate data analysis is demonstrated on the `hbk` data and the `stock611` data which themselves are parts of the package `robustfa` (Zhang 2013). We follow the object-oriented paradigm as applied to the R object model (naming conventions, access methods, coexistence of S3 and S4 classes, usage of UML, etc.) which is described in (Todorov and Filzmoser 2009).

The rest of the paper is organized as follows. In the next Section 2 the design approach and structure of the solution are given. Section 3 describes the robust factor analysis method, some theoretical results, the computations, and the implementations. The Sections 3.1, 3.2, 3.3, and 3.4 are dedicated to the object model, method of robust factor analysis, a `hbk` data example, and a stocks data example, respectively. Section 4 concludes.

## 2. Design approach and structure of the solution

We follow the route of (Todorov and Filzmoser 2009). The main part of the solution is implemented in the package `robustfa` but it relies on codes in the packages `rrcov` (Todorov 2013), `robustbase` (Rousseeuw *et al.* 2013), and `pcaPP` (Filzmoser *et al.* 2013). The structure of the solution and its relation to other R packages are shown in Figure 1. The package `robustfa` extends `rrcov` with options for dealing with robust factor analysis problems like `robust` (Wang *et al.* 2013).

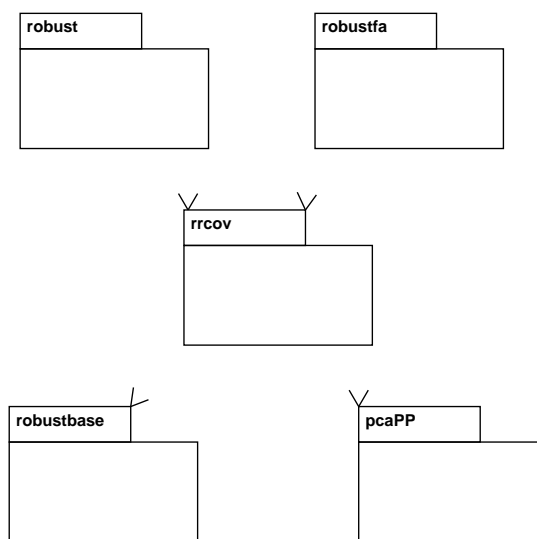

Figure 1: Class diagram: structure of the solution and relation to other R packages.

### 3. Robust factor analysis

#### 3.1. Object model

The object model for the S4 classes and methods implementing the robust factor analysis follows the Unified Modeling Language (UML) (OMG 2009a,b) class diagram and is presented in Figure 2. A class is denoted by a box with three compartments which contain the name, the attributes (slots) and operations (methods) of the class, respectively. The class names, *Fa* and *FaRobust*, in italics indicate that the classes are abstract. Each attribute is followed by its type and each operation is followed by the type of its return value. We use the R types like `numeric`, `vector`, `matrix`, etc. but the type can be also a name of an S4 class (*Fa*, *FaClassic*, or *FaCov*). The classes *Ulogical*, *Unumeric* etc. are class unions for optional slots, e.g., for definition of slots which will be computed on demand. Relationships between classes are denoted by arrows with different form. The inheritance relationship is depicted by a large empty triangular arrowhead pointing to the base class. We see that both *FaClassic* and *FaRobust* inherit from *Fa*, and *FaCov* inherits from *FaRobust*. Composition means that one class contains another one as a slot. This relation is represented by an arrow with a solid diamond on the side of the composed class. We see that *SummaryFa* is a composed class of *Fa*.

As in (Todorov and Filzmoser 2009), all UML diagrams of the solution were created with the open source UML tool **ArgoUML** (Robbins 1999; Robbins and Redmiles 2000) which is available for download from <http://argouml.tigris.org/>. The naming conventions of the solution follow the recommended Sun's Java coding style. See <http://java.sun.com/docs/codeconv/>.

#### 3.2. Factor analysis based on a robust covariance matrix

As in (Todorov and Filzmoser 2009), the most straightforward and intuitive method to obtain robust factor analysis is to replace the classical estimates of location and covariance by their robust analogues. The package `stats` in base R contains the function `factanal()` which performs a factor analysis on a given numeric data matrix and returns the results as an object of S3 class `factanal`. This function has an argument `covmat` which can take a covariance matrix, or a covariance list as returned by `cov.wt`, and if supplied, it is used rather than the covariance matrix of the input data. This allows to obtain robust factor analysis by supplying the covariance matrix computed by `cov.mve` or `cov.mcd` from the package **MASS**. The reason to include such type of function in the solution is the unification of the interfaces by leveraging the object orientation provided by the S4 classes and methods. The function `FaCov()` computes robust factor analysis by replacing the classical covariance matrix with one of the robust covariance estimators available in the package **rrcov**—MCD, OGK, MVE, M, S or Stahel-Donoho, i.e., the parameter `cov.control` can be any object of a class derived from the base class `CovControl`. This control class will be used to compute a robust estimate of the covariance matrix. If this parameter is omitted, MCD will be used by default. Of course any newly developed estimator following the concepts of the framework in (Todorov and Filzmoser 2009) can be used as input to the function `FaCov()`.

There are three methods to perform a factor analysis: maximum likelihood estimation (MLE), principal component analysis (PCA), and principal factor analysis (PFA). The function `factanal()` performs a factor analysis using MLE. The function `FaCov()` deals with three methods using

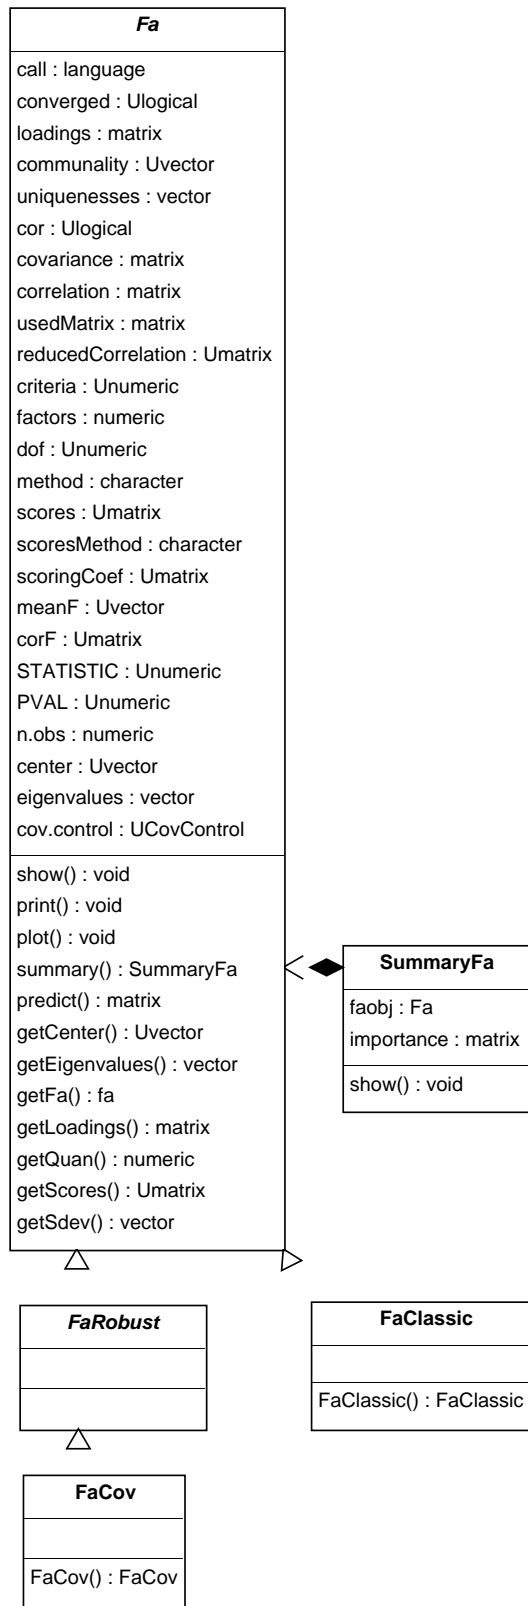

Figure 2: Object model for robust factor analysis.

an argument ‘`method = c("mle", "pca", "pfa")`’. When the data set is large, `factanal()` usually generates errors, and thus one can only resort to the PCA and PFA methods.

When compare the classical and robust factor analysis methods, there are two other issues to consider. That is, whether we should use `data` or `scale(data)` as the data input; whether we should use the covariance matrix or the correlation matrix as the running matrix (used matrix)? Consider the factor analysis methods, the data input, and the running matrix all together, there are 8 combinations, i.e.,

- (1) `classical, x = data, cor = FALSE`
- (2) `classical, x = data, cor = TRUE`
- (3) `classical, x = scale(data), cor = FALSE`
- (4) `classical, x = scale(data), cor = TRUE`
- (5) `robust, x = data, cor = FALSE`
- (6) `robust, x = data, cor = TRUE`
- (7) `robust, x = scale(data), cor = FALSE`
- (8) `robust, x = scale(data), cor = TRUE`

Here `cor` is a logical value indicating whether the calculation should use the covariance matrix (`cor = FALSE`) or the correlation matrix (`cor = TRUE`).

There are 4 classical and robust factor analysis comparisons, i.e., (1) vs (5), (2) vs (6), (3) vs (7), and (4) vs (8). We recommend (4) vs (8). The reasons are as follows. First, when the variables have different units, it is common to standardize the variables, the sample covariance matrix of the standardized variables is the correlation matrix of the original variables. Thus it is common to use the correlation matrix as the running matrix. Second, we need to explain the factors from the loading matrix. The entries of the loading matrix from the sample covariance matrix are not limited between 0 and 1, which makes the explanations of the factors hard. The first two reasons suggest us to choose (2) vs (6) and (4) vs (8). However, (2) and (4) ((6) and (8)) have the same running matrices, eigenvalues, loadings, uniquenesses, scoring coefficients, scaled data matrices, and score matrices, see Theorem 3.2. That is, (2) vs (6) and (4) vs (8) give us the same comparisons. We can choose any pair to do the comparison. Third, we may not be able to compute the robust covariance matrix, and thus the robust correlation matrix of the original data, as the stocks data example will illustrate. Consequently, we should choose (4) vs (8).

The running matrices of the 8 combinations are given in Table 1. In the table,

$$\text{correlation} = \text{cov2cor}(\text{covariance}).$$

Table 1: The running matrices.

		Classical	Robust
data	covariance	(1) $\mathbf{S}^c$	(5) $\mathbf{S}^r$
	correlation	(2) $\mathbf{R}^c$	(6) $\mathbf{R}^r$
scale(data)	covariance	(3) $\tilde{\mathbf{S}}^c$	(7) $\tilde{\mathbf{S}}^r$
	correlation	(4) $\tilde{\mathbf{R}}^c$	(8) $\tilde{\mathbf{R}}^r$

Let  $\mathbf{S} = (s_{ij})_{p \times p}$  be a square matrix. Let  $\mathbf{v} = \text{diag}(\mathbf{S}) = (s_{11}, s_{22}, \dots, s_{pp})^\top$  be a vector holding the diagonal elements of  $\mathbf{S}$ . Let

$$\mathbf{D} = \text{diag}(\mathbf{v}) = \text{diag}(\text{diag}(\mathbf{S})) = \begin{pmatrix} s_{11} & & & \\ & s_{22} & & \\ & & \ddots & \\ & & & s_{pp} \end{pmatrix}$$

be a diagonal matrix whose diagonal is the vector  $\mathbf{v}$ . In fact,

$$\begin{aligned} \text{diag}(\text{matrix}) &= \text{vector}, \\ \text{diag}(\text{vector}) &= \text{diagonal matrix}. \end{aligned}$$

Let

$$\mathbf{X}_{n \times p} = \begin{pmatrix} \mathbf{X}_{(1)}^\top \\ \mathbf{X}_{(2)}^\top \\ \vdots \\ \mathbf{X}_{(n)}^\top \end{pmatrix}$$

be the original data matrix, where  $\mathbf{X}_{(k)} = (x_{k1}, x_{k2}, \dots, x_{kp})^\top$  ( $k = 1, 2, \dots, n$ ) is the  $k$ th observation,  $n$  is the number of observations. Let  $M$  be the number of regular observations (excluding the outliers), without loss of generality, we can assume  $\mathbf{X}_{(1)}, \mathbf{X}_{(2)}, \dots, \mathbf{X}_{(M)}$  as the regular observations. Let

$$\bar{\mathbf{X}} = \frac{1}{n} \sum_{k=1}^n \mathbf{X}_{(k)} = (\bar{x}_1, \bar{x}_2, \dots, \bar{x}_p)^\top$$

be the sample mean of  $\mathbf{X}$ , where

$$\bar{x}_j = \frac{1}{n} \sum_{k=1}^n x_{kj}, \quad j = 1, 2, \dots, p.$$

Let

$$\mathbf{S} = (s_{ij})_{p \times p} = \frac{1}{n-1} \sum_{k=1}^n (\mathbf{X}_{(k)} - \bar{\mathbf{X}}) (\mathbf{X}_{(k)} - \bar{\mathbf{X}})^\top$$

be the sample covariance matrix, where

$$s_{ij} = \frac{1}{n-1} \sum_{k=1}^n (x_{ki} - \bar{x}_i)(x_{kj} - \bar{x}_j), \quad i, j = 1, 2, \dots, p.$$

Let  $\mathbf{X}^*$  be the scaled matrix of  $\mathbf{X}$ , where

$$\begin{aligned}\mathbf{X}^* &= \begin{pmatrix} \mathbf{X}_{(1)}^{*\top} \\ \mathbf{X}_{(2)}^{*\top} \\ \vdots \\ \mathbf{X}_{(n)}^{*\top} \end{pmatrix} = \begin{pmatrix} \left( \mathbf{D}^{-\frac{1}{2}} (\mathbf{X}_{(1)} - \bar{\mathbf{X}}) \right)^\top \\ \left( \mathbf{D}^{-\frac{1}{2}} (\mathbf{X}_{(2)} - \bar{\mathbf{X}}) \right)^\top \\ \vdots \\ \left( \mathbf{D}^{-\frac{1}{2}} (\mathbf{X}_{(n)} - \bar{\mathbf{X}}) \right)^\top \end{pmatrix} \\ &= \begin{pmatrix} (\mathbf{X}_{(1)} - \bar{\mathbf{X}})^\top \mathbf{D}^{-\frac{1}{2}} \\ (\mathbf{X}_{(2)} - \bar{\mathbf{X}})^\top \mathbf{D}^{-\frac{1}{2}} \\ \vdots \\ (\mathbf{X}_{(n)} - \bar{\mathbf{X}})^\top \mathbf{D}^{-\frac{1}{2}} \end{pmatrix} = \begin{pmatrix} \mathbf{X}_{(1)}^\top - \bar{\mathbf{X}}^\top \\ \mathbf{X}_{(2)}^\top - \bar{\mathbf{X}}^\top \\ \vdots \\ \mathbf{X}_{(n)}^\top - \bar{\mathbf{X}}^\top \end{pmatrix} \mathbf{D}^{-\frac{1}{2}} \\ &= (\mathbf{X} - \mathbf{1}\bar{\mathbf{X}}^\top) \mathbf{D}^{-\frac{1}{2}},\end{aligned}$$

$$\mathbf{1} = \mathbf{1}_{n \times 1} = \begin{pmatrix} 1 \\ 1 \\ \vdots \\ 1 \end{pmatrix}_{n \times 1}, \quad \mathbf{D} = \text{diag}(\text{diag}(\mathbf{S})) = \begin{pmatrix} s_{11} & & & \\ & s_{22} & & \\ & & \ddots & \\ & & & s_{pp} \end{pmatrix},$$

$$\mathbf{D}^{\frac{1}{2}} = [\text{diag}(\text{diag}(\mathbf{S}))]^{\frac{1}{2}} = \text{diag}([\text{diag}(\mathbf{S})]^{\frac{1}{2}}) = \begin{pmatrix} \sqrt{s_{11}} & & & \\ & \sqrt{s_{22}} & & \\ & & \ddots & \\ & & & \sqrt{s_{pp}} \end{pmatrix},$$

$$\mathbf{D}^{-\frac{1}{2}} = [\text{diag}(\text{diag}(\mathbf{S}))]^{-\frac{1}{2}} = \text{diag}([\text{diag}(\mathbf{S})]^{-\frac{1}{2}}) = \begin{pmatrix} 1/\sqrt{s_{11}} & & & \\ & 1/\sqrt{s_{22}} & & \\ & & \ddots & \\ & & & 1/\sqrt{s_{pp}} \end{pmatrix},$$

$$\begin{aligned}\mathbf{X}_{(k)}^* &= \mathbf{D}^{-\frac{1}{2}} (\mathbf{X}_{(k)} - \bar{\mathbf{X}}) \\ &= \begin{pmatrix} 1/\sqrt{s_{11}} & & & \\ & 1/\sqrt{s_{22}} & & \\ & & \ddots & \\ & & & 1/\sqrt{s_{pp}} \end{pmatrix} \begin{pmatrix} x_{k1} - \bar{x}_1 \\ x_{k2} - \bar{x}_2 \\ \vdots \\ x_{kp} - \bar{x}_p \end{pmatrix} \\ &= \begin{pmatrix} (x_{k1} - \bar{x}_1) / \sqrt{s_{11}} \\ (x_{k2} - \bar{x}_2) / \sqrt{s_{22}} \\ \vdots \\ (x_{kp} - \bar{x}_p) / \sqrt{s_{pp}} \end{pmatrix}.\end{aligned}$$

To compare the 8 combinations, we summarize some useful results in Tables 2 and 3. There are some points in Tables 2 and 3 that are proved here.

**Proof.** (a)

$$\begin{aligned}
\bar{\mathbf{X}}^{*r} &= \frac{1}{M} \sum_{k=1}^M \mathbf{X}_{(k)}^{*r} \\
&= \frac{1}{M} \sum_{k=1}^M (\mathbf{D}^r)^{-\frac{1}{2}} (\mathbf{X}_{(k)} - \bar{\mathbf{X}}^r) \\
&= (\mathbf{D}^r)^{-\frac{1}{2}} \frac{1}{M} \sum_{k=1}^M (\mathbf{X}_{(k)} - \bar{\mathbf{X}}^r) \\
&= (\mathbf{D}^r)^{-\frac{1}{2}} (\bar{\mathbf{X}}^r - \bar{\mathbf{X}}^r) \\
&= \mathbf{0}.
\end{aligned}$$

(b)

$$\begin{aligned}
\mathbf{S}^{*r} &= \mathbf{R}^r \\
&= \frac{1}{M-1} \sum_{k=1}^M (\mathbf{X}_{(k)}^{*r} - \bar{\mathbf{X}}^{*r}) (\mathbf{X}_{(k)}^{*r} - \bar{\mathbf{X}}^{*r})^\top \\
&= \frac{1}{M-1} \sum_{k=1}^M \mathbf{X}_{(k)}^{*r} (\mathbf{X}_{(k)}^{*r})^\top \\
&= \frac{1}{M-1} \sum_{k=1}^M (\mathbf{D}^r)^{-\frac{1}{2}} (\mathbf{X}_{(k)} - \bar{\mathbf{X}}^r) (\mathbf{X}_{(k)} - \bar{\mathbf{X}}^r)^\top (\mathbf{D}^r)^{-\frac{1}{2}} \\
&= (\mathbf{D}^r)^{-\frac{1}{2}} \left[ \frac{1}{M-1} \sum_{k=1}^M (\mathbf{X}_{(k)} - \bar{\mathbf{X}}^r) (\mathbf{X}_{(k)} - \bar{\mathbf{X}}^r)^\top \right] (\mathbf{D}^r)^{-\frac{1}{2}} \\
&= (\mathbf{D}^r)^{-\frac{1}{2}} \mathbf{S}^r (\mathbf{D}^r)^{-\frac{1}{2}}.
\end{aligned}$$

(c)

$$\begin{aligned}
\bar{\mathbf{Y}}^c &= \frac{1}{n} \sum_{k=1}^n \mathbf{Y}_{(k)} \\
&= \frac{1}{n} \sum_{k=1}^n (\mathbf{D}^c)^{-\frac{1}{2}} (\mathbf{X}_{(k)} - \bar{\mathbf{X}}^c) \\
&= (\mathbf{D}^c)^{-\frac{1}{2}} \frac{1}{n} \sum_{k=1}^n (\mathbf{X}_{(k)} - \bar{\mathbf{X}}^c) \\
&= (\mathbf{D}^c)^{-\frac{1}{2}} (\bar{\mathbf{X}}^c - \bar{\mathbf{X}}^c) \\
&= \mathbf{0}.
\end{aligned}$$

(d) By Theorem 3.1, we have  $\tilde{\mathbf{S}}^c = \mathbf{R}^c$ , thus

$$\begin{aligned}\tilde{\mathbf{D}}^c &= \text{diag} \left( \text{diag} \left( \tilde{\mathbf{S}}^c \right) \right) \\ &= \text{diag} \left( \text{diag} \left( \mathbf{R}^c \right) \right) \\ &= \text{diag} \left( (1, 1, \dots, 1) \right) \\ &= \mathbf{E}.\end{aligned}$$

(e)

$$\begin{aligned}\mathbf{Y}_{(k)}^{*c} &= \left( \tilde{\mathbf{D}}^c \right)^{-\frac{1}{2}} \left( \mathbf{Y}_{(k)} - \bar{\mathbf{Y}}^c \right) \\ &= \mathbf{E}^{-\frac{1}{2}} \left( \mathbf{Y}_{(k)} - \mathbf{0} \right) \\ &= \mathbf{Y}_{(k)}.\end{aligned}$$

(f)

$$\begin{aligned}\bar{\mathbf{Y}}^r &= \frac{1}{M} \sum_{k=1}^M \mathbf{Y}_{(k)} \\ &= \frac{1}{M} \sum_{k=1}^M \left( \mathbf{D}^c \right)^{-\frac{1}{2}} \left( \mathbf{X}_{(k)} - \bar{\mathbf{X}}^c \right) \\ &= \left( \mathbf{D}^c \right)^{-\frac{1}{2}} \frac{1}{M} \sum_{k=1}^M \left( \mathbf{X}_{(k)} - \bar{\mathbf{X}}^c \right) \\ &= \left( \mathbf{D}^c \right)^{-\frac{1}{2}} \left( \bar{\mathbf{X}}^r - \bar{\mathbf{X}}^c \right).\end{aligned}$$

(g)

$$\begin{aligned}\bar{\mathbf{Y}}^{*r} &= \frac{1}{M} \sum_{k=1}^M \mathbf{Y}_{(k)}^{*r} \\ &= \frac{1}{M} \sum_{k=1}^M \left( \tilde{\mathbf{D}}^r \right)^{-\frac{1}{2}} \left( \mathbf{Y}_{(k)} - \bar{\mathbf{Y}}^r \right) \\ &= \left( \tilde{\mathbf{D}}^r \right)^{-\frac{1}{2}} \frac{1}{M} \sum_{k=1}^M \left( \mathbf{Y}_{(k)} - \bar{\mathbf{Y}}^r \right) \\ &= \left( \tilde{\mathbf{D}}^r \right)^{-\frac{1}{2}} \left( \bar{\mathbf{Y}}^r - \bar{\mathbf{Y}}^r \right) \\ &= \mathbf{0}.\end{aligned}$$

(h)

$$\begin{aligned}
\tilde{\mathbf{S}}^{*r} &= \tilde{\mathbf{R}}^r \\
&= \frac{1}{M-1} \sum_{k=1}^M \left( \mathbf{Y}_{(k)}^{*r} - \bar{\mathbf{Y}}^{*r} \right) \left( \mathbf{Y}_{(k)}^{*r} - \bar{\mathbf{Y}}^{*r} \right)^\top \\
&= \frac{1}{M-1} \sum_{k=1}^M \mathbf{Y}_{(k)}^{*r} \left( \mathbf{Y}_{(k)}^{*r} \right)^\top \\
&= \frac{1}{M-1} \sum_{k=1}^M \left( \tilde{\mathbf{D}}^r \right)^{-\frac{1}{2}} \left( \mathbf{Y}_{(k)} - \bar{\mathbf{Y}}^r \right) \left( \mathbf{Y}_{(k)} - \bar{\mathbf{Y}}^r \right)^\top \left( \tilde{\mathbf{D}}^r \right)^{-\frac{1}{2}} \\
&= \left( \tilde{\mathbf{D}}^r \right)^{-\frac{1}{2}} \left[ \frac{1}{M-1} \sum_{k=1}^M \left( \mathbf{Y}_{(k)} - \bar{\mathbf{Y}}^r \right) \left( \mathbf{Y}_{(k)} - \bar{\mathbf{Y}}^r \right)^\top \right] \left( \tilde{\mathbf{D}}^r \right)^{-\frac{1}{2}} \\
&= \left( \tilde{\mathbf{D}}^r \right)^{-\frac{1}{2}} \tilde{\mathbf{S}}^r \left( \tilde{\mathbf{D}}^r \right)^{-\frac{1}{2}}.
\end{aligned}$$

Define the multiplication of two vectors by

$$\begin{aligned}
\mathbf{x} \cdot \mathbf{y} &= (x_1, x_2, \dots, x_p) \cdot (y_1, y_2, \dots, y_p) \\
&= (x_1 y_1, x_2 y_2, \dots, x_p y_p).
\end{aligned}$$

To prove Theorem 3.1, we need the following lemma.

**Lemma 3.1** *Let*

$$\mathbf{\Lambda}_1 = \begin{pmatrix} \lambda_1 & & & \\ & \lambda_2 & & \\ & & \ddots & \\ & & & \lambda_p \end{pmatrix}, \quad \mathbf{\Lambda}_2 = \begin{pmatrix} \mu_1 & & & \\ & \mu_2 & & \\ & & \ddots & \\ & & & \mu_p \end{pmatrix}, \quad \mathbf{A} = (a_{ij})_{p \times p}.$$

Then

$$\begin{aligned}
\text{diag}(\mathbf{\Lambda}_1 \mathbf{A} \mathbf{\Lambda}_2) &= \text{diag}(\mathbf{\Lambda}_1) \cdot \text{diag}(\mathbf{A}) \cdot \text{diag}(\mathbf{\Lambda}_2), \\
\text{diag}(\mathbf{\Lambda}_1 \mathbf{\Lambda}_2) &= \text{diag}(\mathbf{\Lambda}_1) \cdot \text{diag}(\mathbf{\Lambda}_2).
\end{aligned}$$

**Proof.**

$$\begin{aligned}
\mathbf{\Lambda}_1 \mathbf{A} \mathbf{\Lambda}_2 &= \begin{pmatrix} \lambda_1 & & & \\ & \lambda_2 & & \\ & & \ddots & \\ & & & \lambda_p \end{pmatrix} \begin{pmatrix} a_{11} & a_{12} & \cdots & a_{1p} \\ a_{21} & a_{22} & \cdots & a_{2p} \\ \vdots & \vdots & \ddots & \vdots \\ a_{p1} & a_{p2} & \cdots & a_{pp} \end{pmatrix} \begin{pmatrix} \mu_1 & & & \\ & \mu_2 & & \\ & & \ddots & \\ & & & \mu_p \end{pmatrix} \\
&= \begin{pmatrix} \lambda_1 a_{11} \mu_1 & * & \cdots & * \\ * & \lambda_2 a_{22} \mu_2 & \cdots & * \\ \vdots & \vdots & \ddots & \vdots \\ * & * & \cdots & \lambda_p a_{pp} \mu_p \end{pmatrix},
\end{aligned}$$

$$\begin{aligned}
\text{diag}(\mathbf{\Lambda}_1 \mathbf{A} \mathbf{\Lambda}_2) &= (\lambda_1 a_{11} \mu_1, \lambda_2 a_{22} \mu_2, \dots, \lambda_p a_{pp} \mu_p) \\
&= (\lambda_1, \lambda_2, \dots, \lambda_p) \cdot (a_{11}, a_{22}, \dots, a_{pp}) \cdot (\mu_1, \mu_2, \dots, \mu_p) \\
&= \text{diag}(\mathbf{\Lambda}_1) \cdot \text{diag}(\mathbf{A}) \cdot \text{diag}(\mathbf{\Lambda}_2).
\end{aligned}$$

$$\mathbf{\Lambda}_1 \mathbf{\Lambda}_2 = \begin{pmatrix} \lambda_1 & & & \\ & \lambda_2 & & \\ & & \ddots & \\ & & & \lambda_p \end{pmatrix} \begin{pmatrix} \mu_1 & & & \\ & \mu_2 & & \\ & & \ddots & \\ & & & \mu_p \end{pmatrix} = \begin{pmatrix} \lambda_1 \mu_1 & & & \\ & \lambda_2 \mu_2 & & \\ & & \ddots & \\ & & & \lambda_p \mu_p \end{pmatrix},$$

$$\begin{aligned}
\text{diag}(\mathbf{\Lambda}_1 \mathbf{\Lambda}_2) &= (\lambda_1 \mu_1, \lambda_2 \mu_2, \dots, \lambda_p \mu_p) \\
&= (\lambda_1, \lambda_2, \dots, \lambda_p) \cdot (\mu_1, \mu_2, \dots, \mu_p) \\
&= \text{diag}(\mathbf{\Lambda}_1) \cdot \text{diag}(\mathbf{\Lambda}_2).
\end{aligned}$$

□

**Theorem 3.1** (a)  $\mathbf{R}^c = \tilde{\mathbf{S}}^c = \tilde{\mathbf{R}}^c$ . (b)  $\mathbf{R}^r = \tilde{\mathbf{R}}^r$ .

**Proof.** (a) We prove  $\mathbf{R}^c = \tilde{\mathbf{S}}^c$  first. Since  $\mathbf{Y}_{(k)} = (\mathbf{D}^c)^{-\frac{1}{2}} (\mathbf{X}_{(k)} - \bar{\mathbf{X}}^c) = \mathbf{X}_{(k)}^{*c}$ ,

$$\begin{aligned}
\mathbf{R}^c &= \frac{1}{n-1} \sum_{k=1}^n \mathbf{X}_{(k)}^{*c} (\mathbf{X}_{(k)}^{*c})^\top \\
&= \frac{1}{n-1} \sum_{k=1}^n \mathbf{Y}_{(k)} \mathbf{Y}_{(k)}^\top \\
&= \tilde{\mathbf{S}}^c.
\end{aligned}$$

Next we prove  $\tilde{\mathbf{R}}^c = \tilde{\mathbf{S}}^c$ . From Table 3 (e), we have  $\mathbf{Y}_{(k)}^{*c} = \mathbf{Y}_{(k)}$ , thus

$$\begin{aligned}
\tilde{\mathbf{R}}^c &= \frac{1}{n-1} \sum_{k=1}^n \mathbf{Y}_{(k)}^{*c} (\mathbf{Y}_{(k)}^{*c})^\top \\
&= \frac{1}{n-1} \sum_{k=1}^n \mathbf{Y}_{(k)} \mathbf{Y}_{(k)}^\top \\
&= \tilde{\mathbf{S}}^c.
\end{aligned}$$

(b) We have

$$\begin{aligned}
\mathbf{R}^r &= \mathbf{S}^{*r} = \frac{1}{M-1} \sum_{k=1}^M \mathbf{X}_{(k)}^{*r} (\mathbf{X}_{(k)}^{*r})^\top, \\
\tilde{\mathbf{R}}^r &= \tilde{\mathbf{S}}^{*r} = \frac{1}{M-1} \sum_{k=1}^M \mathbf{Y}_{(k)}^{*r} (\mathbf{Y}_{(k)}^{*r})^\top.
\end{aligned}$$

To prove that  $\mathbf{R}^r = \tilde{\mathbf{R}}^r$ , it suffices to prove that

$$\mathbf{X}_{(k)}^{*r} = \mathbf{Y}_{(k)}^{*r}. \quad (3.1)$$

Write

$$\begin{aligned} \mathbf{X}_{(k)}^{*r} &= (\mathbf{D}^r)^{-\frac{1}{2}} (\mathbf{X}_{(k)} - \bar{\mathbf{X}}^r), \\ \mathbf{Y}_{(k)}^{*r} &= (\tilde{\mathbf{D}}^r)^{-\frac{1}{2}} (\mathbf{Y}_{(k)} - \bar{\mathbf{Y}}^r), \\ \mathbf{Y}_{(k)} &= (\mathbf{D}^c)^{-\frac{1}{2}} (\mathbf{X}_{(k)} - \bar{\mathbf{X}}^c), \end{aligned}$$

from Table 3 (f), we have

$$\bar{\mathbf{Y}}^r = (\mathbf{D}^c)^{-\frac{1}{2}} (\bar{\mathbf{X}}^r - \bar{\mathbf{X}}^c).$$

Thus

$$\begin{aligned} \mathbf{Y}_{(k)}^{*r} &= (\tilde{\mathbf{D}}^r)^{-\frac{1}{2}} (\mathbf{Y}_{(k)} - \bar{\mathbf{Y}}^r) \\ &= (\tilde{\mathbf{D}}^r)^{-\frac{1}{2}} \left[ (\mathbf{D}^c)^{-\frac{1}{2}} (\mathbf{X}_{(k)} - \bar{\mathbf{X}}^c) - (\mathbf{D}^c)^{-\frac{1}{2}} (\bar{\mathbf{X}}^r - \bar{\mathbf{X}}^c) \right] \\ &= (\tilde{\mathbf{D}}^r)^{-\frac{1}{2}} (\mathbf{D}^c)^{-\frac{1}{2}} (\mathbf{X}_{(k)} - \bar{\mathbf{X}}^r). \end{aligned}$$

To prove (3.1), it suffices to prove

$$(\tilde{\mathbf{D}}^r)^{-\frac{1}{2}} (\mathbf{D}^c)^{-\frac{1}{2}} = (\mathbf{D}^r)^{-\frac{1}{2}},$$

which reduces to prove

$$\tilde{\mathbf{D}}^r \mathbf{D}^c = \mathbf{D}^r,$$

that is,

$$\text{diag} \left( \text{diag} \left( \tilde{\mathbf{S}}^r \right) \right) \cdot \text{diag} \left( \text{diag} \left( \mathbf{S}^c \right) \right) = \text{diag} \left( \text{diag} \left( \mathbf{S}^r \right) \right),$$

which is equivalent to

$$\text{diag} \left( \tilde{\mathbf{S}}^r \right) \cdot \text{diag} \left( \mathbf{S}^c \right) = \text{diag} \left( \mathbf{S}^r \right).$$

We have just proved

$$\mathbf{Y}_{(k)} - \bar{\mathbf{Y}}^r = (\mathbf{D}^c)^{-\frac{1}{2}} (\mathbf{X}_{(k)} - \bar{\mathbf{X}}^r),$$

and thus

$$\begin{aligned} \tilde{\mathbf{S}}^r &= \frac{1}{M-1} \sum_{k=1}^M (\mathbf{Y}_{(k)} - \bar{\mathbf{Y}}^r) (\mathbf{Y}_{(k)} - \bar{\mathbf{Y}}^r)^\top \\ &= \frac{1}{M-1} \sum_{k=1}^M (\mathbf{D}^c)^{-\frac{1}{2}} (\mathbf{X}_{(k)} - \bar{\mathbf{X}}^r) (\mathbf{X}_{(k)} - \bar{\mathbf{X}}^r)^\top (\mathbf{D}^c)^{-\frac{1}{2}} \\ &= (\mathbf{D}^c)^{-\frac{1}{2}} \left[ \frac{1}{M-1} \sum_{k=1}^M (\mathbf{X}_{(k)} - \bar{\mathbf{X}}^r) (\mathbf{X}_{(k)} - \bar{\mathbf{X}}^r)^\top \right] (\mathbf{D}^c)^{-\frac{1}{2}} \\ &= (\mathbf{D}^c)^{-\frac{1}{2}} \mathbf{S}^r (\mathbf{D}^c)^{-\frac{1}{2}}. \end{aligned}$$

Consequently,

$$\begin{aligned}
\text{diag}(\tilde{\mathbf{S}}^r) &= \text{diag}\left((\mathbf{D}^c)^{-\frac{1}{2}} \mathbf{S}^r (\mathbf{D}^c)^{-\frac{1}{2}}\right) \\
&= \text{diag}\left((\mathbf{D}^c)^{-\frac{1}{2}}\right) \cdot \text{diag}(\mathbf{S}^r) \cdot \text{diag}\left((\mathbf{D}^c)^{-\frac{1}{2}}\right) \quad (\text{Lemma 3.1}) \\
&= \text{diag}\left((\mathbf{D}^c)^{-\frac{1}{2}}\right) \cdot \text{diag}\left((\mathbf{D}^c)^{-\frac{1}{2}}\right) \cdot \text{diag}(\mathbf{S}^r) \\
&= \text{diag}\left((\mathbf{D}^c)^{-1}\right) \cdot \text{diag}(\mathbf{S}^r) \quad (\text{Lemma 3.1}).
\end{aligned}$$

Finally,

$$\begin{aligned}
\text{diag}(\tilde{\mathbf{S}}^r) \cdot \text{diag}(\mathbf{S}^c) &= \text{diag}\left((\mathbf{D}^c)^{-1}\right) \cdot \text{diag}(\mathbf{S}^r) \cdot \text{diag}(\mathbf{S}^c) \\
&= \text{diag}\left((\mathbf{D}^c)^{-1}\right) \cdot \text{diag}(\mathbf{S}^r) \cdot \text{diag}(\mathbf{D}^c) \\
&= \text{diag}\left((\mathbf{D}^c)^{-1}\right) \cdot \text{diag}(\mathbf{D}^c) \cdot \text{diag}(\mathbf{S}^r) \\
&= \text{diag}(\mathbf{E}) \cdot \text{diag}(\mathbf{S}^r) \quad (\text{Lemma 3.1}) \\
&= \text{diag}(\mathbf{S}^r).
\end{aligned}$$

The proof is complete.  $\square$

The score of the  $k$ th observation is summarized in Table 4. The scores method can be “regression” or “Bartlett”. The running matrix can be the covariance matrix ( $\mathbf{S}$ ) or the correlation matrix ( $\mathbf{R}$ ).

Table 4: The score of the  $k$ th observation.

	regression	Bartlett
cor = FALSE	$\tilde{\mathbf{f}}_{(k)} = \hat{\mathbf{L}}^\top \mathbf{S}^{-1} (\mathbf{X}_{(k)} - \bar{\mathbf{X}})$	$\hat{\mathbf{f}}_{(k)} = \left(\hat{\mathbf{L}}^\top \hat{\Psi}^{-1} \hat{\mathbf{L}}\right)^{-1} \hat{\mathbf{L}}^\top \hat{\Psi}^{-1} (\mathbf{X}_{(k)} - \bar{\mathbf{X}})$
cor = TRUE	$\tilde{\mathbf{f}}_{(k)}^* = \hat{\mathbf{L}}^{*\top} \mathbf{R}^{-1} \mathbf{X}_{(k)}^*$	$\hat{\mathbf{f}}_{(k)}^* = \left(\hat{\mathbf{L}}^{*\top} \hat{\Psi}^{*-1} \hat{\mathbf{L}}^*\right)^{-1} \hat{\mathbf{L}}^{*\top} \hat{\Psi}^{*-1} \mathbf{X}_{(k)}^*$

If we define the scoring coefficient  $\mathbf{S}_c$  by

$$\mathbf{S}_c = \begin{cases} \hat{\mathbf{L}}^\top \mathbf{S}^{-1}, & \text{cor} = \text{FALSE}, \text{scoresMethod} = \text{“regression”}, \\ \left(\hat{\mathbf{L}}^\top \hat{\Psi}^{-1} \hat{\mathbf{L}}\right)^{-1} \hat{\mathbf{L}}^\top \hat{\Psi}^{-1}, & \text{cor} = \text{FALSE}, \text{scoresMethod} = \text{“Bartlett”}, \\ \hat{\mathbf{L}}^{*\top} \mathbf{R}^{-1}, & \text{cor} = \text{TRUE}, \text{scoresMethod} = \text{“regression”}, \\ \left(\hat{\mathbf{L}}^{*\top} \hat{\Psi}^{*-1} \hat{\mathbf{L}}^*\right)^{-1} \hat{\mathbf{L}}^{*\top} \hat{\Psi}^{*-1}, & \text{cor} = \text{TRUE}, \text{scoresMethod} = \text{“Bartlett”}, \end{cases}$$

then the score of the  $k$ th observation simplifies to

$$\mathbf{f}_{(k)} = \begin{cases} \mathbf{S}_c (\mathbf{X}_{(k)} - \bar{\mathbf{X}}), & \text{cor} = \text{FALSE}, \\ \mathbf{S}_c \mathbf{X}_{(k)}^*, & \text{cor} = \text{TRUE}. \end{cases}$$

If `cor = FALSE`, then the score matrix is

$$\mathbf{F} = \begin{pmatrix} \mathbf{f}_{(1)}^\top \\ \mathbf{f}_{(2)}^\top \\ \vdots \\ \mathbf{f}_{(n)}^\top \end{pmatrix} = \begin{pmatrix} (\mathbf{X}_{(1)} - \bar{\mathbf{X}})^\top \mathbf{S}_c^\top \\ (\mathbf{X}_{(2)} - \bar{\mathbf{X}})^\top \mathbf{S}_c^\top \\ \vdots \\ (\mathbf{X}_{(n)} - \bar{\mathbf{X}})^\top \mathbf{S}_c^\top \end{pmatrix} = \begin{pmatrix} (\mathbf{X}_{(1)} - \bar{\mathbf{X}})^\top \\ (\mathbf{X}_{(2)} - \bar{\mathbf{X}})^\top \\ \vdots \\ (\mathbf{X}_{(n)} - \bar{\mathbf{X}})^\top \end{pmatrix} \mathbf{S}_c^\top = (\mathbf{X} - \mathbf{1}\bar{\mathbf{X}}^\top) \mathbf{S}_c^\top.$$

If `cor = TRUE`, then the score matrix is

$$\mathbf{F} = \begin{pmatrix} \mathbf{f}_{(1)}^\top \\ \mathbf{f}_{(2)}^\top \\ \vdots \\ \mathbf{f}_{(n)}^\top \end{pmatrix} = \begin{pmatrix} \mathbf{X}_{(1)}^{*\top} \mathbf{S}_c^\top \\ \mathbf{X}_{(2)}^{*\top} \mathbf{S}_c^\top \\ \vdots \\ \mathbf{X}_{(n)}^{*\top} \mathbf{S}_c^\top \end{pmatrix} = \begin{pmatrix} \mathbf{X}_{(1)}^{*\top} \\ \mathbf{X}_{(2)}^{*\top} \\ \vdots \\ \mathbf{X}_{(n)}^{*\top} \end{pmatrix} \mathbf{S}_c^\top = \mathbf{X}^* \mathbf{S}_c^\top,$$

where  $\mathbf{X}^* = (\mathbf{X} - \mathbf{1}\bar{\mathbf{X}}^\top) \mathbf{D}^{-\frac{1}{2}}$ . If we define

$$\text{scaledX} = \begin{cases} \mathbf{X} - \mathbf{1}\bar{\mathbf{X}}^\top, & \text{cor} = \text{FALSE}, \\ \mathbf{X}^*, & \text{cor} = \text{TRUE}, \end{cases}$$

then

$$\mathbf{F} = \text{scaledX} \cdot \mathbf{S}_c^\top. \quad (3.2)$$

**Theorem 3.2** *The running matrices ( $\mathbf{R}$ ), eigenvalues ( $\lambda$ ), loadings ( $\mathbf{L}$ ), uniquenesses ( $\Psi$ ), scoring coefficients ( $\mathbf{S}_c$ ), scaled data matrices (scaledX), score matrices ( $\mathbf{F}$ ) are the same for*

- (a) combinations (2) and (4),
- (b) combinations (6) and (8).

**Proof.** If the running matrices ( $\mathbf{R}$ ) are the same, then the eigenvalues ( $\lambda$ ), loadings ( $\mathbf{L}$ ), uniquenesses ( $\Psi$ ) are the same. If  $\mathbf{R}, \mathbf{L}, \Psi$  are the same, then by the definition of scoring coefficient  $\mathbf{S}_c$ , we know that  $\mathbf{S}_c$  are the same. If the scaled data matrices (scaledX) are the same, then by (3.2), the score matrices ( $\mathbf{F}$ ) are the same. Thus it suffices to show that  $\mathbf{R}$  and scaledX are the same.

(a) The running matrices  $\mathbf{R}^c = \tilde{\mathbf{R}}^c$  by Theorem 3.1. From Table 3, we see that

$$\mathbf{Y}_{(k)}^{*c} = \mathbf{Y}_{(k)} = \mathbf{X}_{(k)}^{*c},$$

thus the scaledX are the same.

(b) The running matrices  $\mathbf{R}^r = \tilde{\mathbf{R}}^r$  by Theorem 3.1. By (3.1), we have  $\mathbf{X}_{(k)}^{*r} = \mathbf{Y}_{(k)}^{*r}$ , thus the scaledX are the same.  $\square$

### 3.3. Example: hbk data

In this subsection, a data set `hbk` is used to show the base functionalities of the robust factor analysis solution. The Hawkins, Bradu and Kass data set `hbk` is from the package `robustbase` consists of 75 observations in 4 dimensions (one response and three explanatory variables). The first 10 observations are bad leverage points, and the next four points are good leverage

points (i.e., their  $\mathbf{x}$  are outlying, but the corresponding  $\mathbf{y}$  fit the model quite well). We will consider only the X-part of the data.

Robust factor analysis is represented by the class `FaCov` which inherits from class `Fa` by class `FaRobust` of distance 2, and uses all slots and methods defined from `Fa`. The function `FaCov()` serves as a constructor (generating function) of the class. It can be called either by providing a data frame or matrix or a formula with no response variable, referring only to numeric variables. The usage of the default method of `FaCov` is:

```
FaCov(x, factors = 2, cor = FALSE, cov.control = CovControlMcd(),
method = c("mle", "pca", "pfa"),
scoresMethod = c("none", "regression", "Bartlett"), ...)
```

where `x` is a numeric matrix or an object that can be coerced to a numeric matrix. `factors` is the number of factors to be fitted. `cor` is a logical value indicating whether the calculation should use the correlation matrix (`cor = TRUE`) or the covariance matrix (`cor = FALSE`). `cov.control` specifies which covariance estimator to use by providing a `CovControl`-class object. The default is `CovControlMcd`-class which will indirectly call `CovMcd`. If `cov.control = NULL` is specified, the classical estimates will be used by calling `CovClassic`. `method` is the method of factor analysis, one of "mle" (the default), "pca", and "pfa". `scoresMethod` specifies which type of scores to produce. The default is "none", "regression" gives Thompson's scores, and "Bartlett" gives Bartlett's weighted least-squares scores (Johnson and Wichern 2007; Xue and Chen 2007). The usage of the formula interface of `FaCov` is:

```
FaCov(formula, data = NULL, factors = 2, cor = FALSE,
method = "mle", scoresMethod = "none", ...)
```

where `formula` is a formula with no response variable, referring only to numeric variables. `data` is an optional data frame containing the variables in the `formula`. Classical factor analysis is represented by the class `FaClassic` which inherits directly from `Fa`, and uses all slots and methods defined there. The function `FaClassic()` serves as a constructor (generating function) of the class. It also has its default method and formula interface as `FaCov()`.

The code lines

```
R> ##
R> ## faCovPcaRegMcd is obtained from FaCov.default
R> ##
R> faCovPcaRegMcd = FaCov(x = hbk.x, factors = 2, method = "pca",
+ scoresMethod = "regression", cov.control = CovControlMcd());
R> faCovPcaRegMcd
```

generate an object `faCovPcaRegMcd` of class `FaCov`. In fact, it is equivalent to use the formula interface

```
R> faCovForPcaRegMcd = FaCov(~., data = as.data.frame(hbk.x),
+ factors = 2, method = "pca", scoresMethod = "regression",
+ cov.control = CovControlMcd())
```

That is `faCovForPcaRegMcd = faCovPcaRegMcd`. Type

```
R> class(faCovPcaRegMcd)
```

```
[1] "FaCov"
attr("package")
[1] "robustfa"
```

We see that the class `FaCov` is defined in the package **robustfa**. For an object `obj` of class `Fa`, we have

```
obj = show(obj) = print(obj) = myFaPrint(obj).
```

Here `show()` and `print()` are S4 generic functions, while `myFaPrint()` is an S3 function acting as a function definition for `setMethod` of the generic functions `show` and `print`.

```
R> show(faCovPcaRegMcd)
```

Call:

```
FaCov(x = hbk.x, factors = 2, cov.control = CovControlMcd(),
      method = "pca", scoresMethod = "regression")
```

Standard deviations:

```
[1] 1.391072 1.261732 1.170626
```

Loadings:

	Factor1	Factor2
X1	-0.004150242	1.2079697
X2	1.180797866	-0.1246965
X3	0.646169668	0.4903801

From Figure 2 we see that `summary()` generates an object of class `SummaryFa` which has its own `show()` method.

```
R> summaryFaCovPcaRegMcd = summary(faCovPcaRegMcd);
R> summaryFaCovPcaRegMcd
```

Call:

```
FaCov(x = hbk.x, factors = 2, cov.control = CovControlMcd(),
      method = "pca", scoresMethod = "regression")
```

Importance of components:

	Factor1	Factor2
SS loadings	1.812	1.715
Proportion Var	0.370	0.350
Cumulative Var	0.370	0.720

From the `summary` result of `faCovPcaRegMcd`, we see that the first two factors account for about 72.0% of its total variance.

Next we calculate prediction/scores using `predict()`. The usage is `predict(object, ...)`, where `object` is an object of class `Fa`. If missing `...(newdata)`, the `scores` slot of `object` is used. To save space, only the first five and last five rows of the scores are displayed.

```
R> predict(faCovPcaRegMcd)
```

```
      Factor1  Factor2
1  20.1391070 10.4105484
2  20.9770640 10.0136763
3  21.3980990 11.4405912
4  22.5484289 10.8723961
5  22.0558985 11.0589128
71  0.6381775  0.5281550
72  0.1462415 -0.7438318
73  0.2005665 -0.7383855
74  0.3525364 -1.1721414
75 -0.5293472 -0.4594629
```

If not missing `...`, then `...` must have the name `newdata`. Moreover, `newdata` should be scaled first. For example, the original data is `x = hbk.x`, and `newdata` is a one row `data.frame`.

```
R> newdata = hbk.x[1, ]
R> cor = FALSE # the default
R> newdata = { if (cor == TRUE)
+             # standardized transformation
+             scale(newdata, center = faCovPcaRegMcd@center,
+             scale = sqrt(diag(faCovPcaRegMcd@covariance)))
+             else # cor == FALSE
+             # centralized transformation
+             scale(newdata, center = faCovPcaRegMcd@center, scale = FALSE)
+             }
```

Finally we get

```
R> prediction = predict(faCovPcaRegMcd, newdata = newdata)
R> prediction
```

```
      Factor1  Factor2
1  20.13911  10.41055
```

One can easily check that

```
prediction = predict(faCovPcaRegMcd)[1,] = faCovPcaRegMcd@scores[1,]
```

To visualize the factor analysis results, the `plot` method can be used. We have `setMethod plot` with signature

```
x = "Fa", y = "missing".
```

The usage is

```
plot(x, which = c("factorScore", "screeplot"), choices = 1:2).
```

Where `x` is an object of class `Fa`. The argument `which` indicates what kind of plot. If `which = "factorScore"`, then a scatterplot of the factor scores is produced; if `which = "screeplot"`, then the eigenvalues plot is created and is helpful to select the number of factors. The argument `choices` is an integer vector of length two indicating which columns of the factor scores to plot. To see how `plot` is functioning, we first generate an `Fa` object.

```
R> faClassicPcaReg = FaClassic(x = hbk.x, factors = 2, method = "pca",
+ scoresMethod = "regression"); faClassicPcaReg
```

Call:

```
FaClassic(x = hbk.x, factors = 2, method = "pca", scoresMethod = "regression")
```

Standard deviations:

```
[1] 14.7024532  1.4075073  0.9572508
```

Loadings:

	Factor1	Factor2
X1	3.411036	0.936662
X2	7.278529	3.860723
X3	11.270812	3.273734

```
R> summary(faClassicPcaReg)
```

Call:

```
FaClassic(x = hbk.x, factors = 2, method = "pca", scoresMethod = "regression")
```

Importance of components:

	Factor1	Factor2
SS loadings	191.643	26.500
Proportion Var	0.875	0.121
Cumulative Var	0.875	0.996

`faClassicPcaReg` is an object of class `FaClassic`. From the `summary` result of `faClassicPcaReg`, we see that the first two factors account for about 99.6% of its total variance. Next we generate an object `faCovPcaRegMcd` of class `FaCov` using the same data set. The `show` and `summary` results have already been shown before.

The following code lines generate classical and robust scatterplots of the first two factor scores. See Figure 3.

```
R> usr <- par(mfrow=c(1,2))
R> plot(faClassicPcaReg, which = "factorScore", choices = 1:2)
R> plot(faCovPcaRegMcd, which = "factorScore", choices = 1:2)
R> par(usr)
```

Figure 3: Classical and robust scatterplots of the first two factor scores of the hbk data.

The following code lines generate classical and robust scree plots. See Figure 4.

```
R> usr <- par(mfrow=c(1,2))
R> plot(faClassicPcaReg, which = "screeplot")
R> plot(faCovPcaRegMcd, which = "screeplot")
R> par(usr)
```

Next we impose a 97.5% tolerance ellipse on the scatterplot of the first two factor scores of the hbk data by using a function `rrcov:::myellipse`. See Figure 5. The left panel shows the classical 97.5% tolerance ellipse, which is very large and contains the outliers 1-13. The regular points are not well separated from the outliers. The right panel shows the robust 97.5% tolerance ellipse which clearly separates the regular points and outliers. We see that the estimate of the center of the regular points is located at the origin (where the mean of the scores should be located). The following code lines compute the means of the classical and robust scores. We see that the mean of all observations of the classical scores equals 0, while the mean of good observations (regular points, excluding the outliers) of the robust scores equals 0.

```
R> colMeans(faClassicPcaReg@scores)
```

```
      Factor1      Factor2
-1.452310e-16  3.376871e-16
```

```
R> colMeans(faCovPcaRegMcd@scores)
```

Figure 4: Classical and robust scree plots of the hbk data.

Figure 5: Classical and robust scatterplot of the first two factor scores of the hbk data with a 97.5% tolerance ellipse.

```
Factor1 Factor2
4.272569 2.072818
```

```
R> colMeans(faClassicPcaReg@scores[15:75,])
```

```
Factor1 Factor2
-0.4523799 -0.1358260
```

```
R> colMeans(faCovPcaRegMcd@scores[15:75,])
```

```
Factor1 Factor2
-8.167419e-17 -3.185066e-18
```

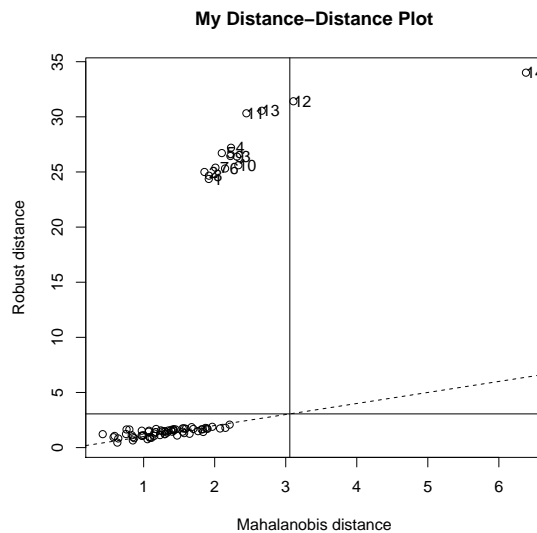

Figure 6: A distance-distance plot for hbk data.

Next we plot a `Cov-class`. See Figure 6. The figure shows a distance-distance plot. We see that the robust (mahalanobis) distances are far larger than the (classical) mahalanobis distances. The outliers have large robust distances. The figure is generated by `myplotDD(x = covMcd)`. `myplotDD()` is a revised version of `.myddplot()` in `plot-utils.R` in the package `rrcov`. In `myplotDD()`, `id.n` and `ind` are printed out. Here `id.n` is the number of observations to identify by a label. By default, the number of observations with robust distances larger than `cutoff` is used. By default `cutoff = sqrt(qchisq(0.975, p))`. `ind` is the index of robust distances whose values are larger than `cutoff`.

```
cutoff = 3.057516
```

```
id.n <- length(which(rd>cutoff))
```

```
id.n = 14
```

Here `y` is the robust distance (`rd`).

`sort.y` = (To save space, only the smallest five and largest five elements of `sort.y$x` and `sort.y$ix` are shown.)

```
$x
      67      18      72      71      28      4
0.4553524 0.6505517 0.7631246 0.8306446 0.8570290 27.1972578
      11      13      12      14
30.3225470 30.5536038 31.4123574 34.0079508
```

```
$ix
[1] 67 18 72 71 28 4 11 13 12 14
```

```
ind =

[1] 1 8 2 6 7 10 3 9 5 4 11 13 12 14
```

From the above results we see that the `cutoff` is computed as 3.057516. There are `id.n` = 14 observations with robust distance larger than `cutoff`. `sort.y` is a list containing the sorted values of `y` (the robust distance). `sort.y$x` is arranged in increasing order. To save space, only the smallest five and largest five robust distances with their indices are shown. `sort.y$ix` contains the indices. `ind` shows the indices of the largest `id.n` = 14 observations whose robust distances are larger than `cutoff`.

The accessor functions `getCenter()`, `getEigenvalues()`, `getLoadings()`, `getQuan()`, `getScores()`, and `getSdev()` are used to access the corresponding slots. For instance

```
R> getEigenvalues(faCovPcaRegMcd)
```

```
[1] 1.935081 1.591967 1.370366
```

The function `getFa()`, which is used in `predict()` and `screepplot()`, returns a list of class `"fa"`.

Note that our previous comparisons in this subsection are just (1) vs (5), i.e., classical and robust factor analysis comparisons using `x = hbk.x` as the data input and the covariance matrix (`cor = FALSE`) as the running matrix.

For `x = hbk.x`, we checked that  $\mathbf{S}^r \neq \tilde{\mathbf{S}}^r$ , and  $\mathbf{R}^r = \tilde{\mathbf{R}}^r$  for `control = "mcd", "ogk", "m", "mve", "sfast", "bisquare", "rocke"`, small differences between  $\mathbf{R}^r$  and  $\tilde{\mathbf{R}}^r$  for `control = "sde", "surreal"`. The results illustrate Theorem 3.1.

The eigenvalues of the running matrices of the `hbk` data of the 8 combinations are given in Table 5. From Table 5 we see that the eigenvalues of (2), (3), and (4) are the same, the eigenvalues of (6) and (8) are the same. The results illustrate Theorems 3.1 and 3.2.

Classical and robust (MCD) scatterplots of the first two factor scores of the `hbk` data with 97.5% tolerance ellipses are plotted in Figure 7. We see that the scores of (2), (3), and (4) are the same, the scores of (6) and (8) are the same, in agree with Theorem 3.2. Note that

Table 5: The eigenvalues of the running matrices for hbk data.

		Classical	Robust (MCD)
hbk.x	covariance	(1) 216.162129 1.981077 0.916329	(5) 1.935081 1.591967 1.370366
	correlation	(2) 2.92435228 0.05668483 0.01896288	(6) 1.1890834 0.9563255 0.8545911
scale(hbk.x)	covariance	(3) 2.92435228 0.05668483 0.01896288	(7) 0.12408511 0.02501676 0.01089401
	correlation	(4) 2.92435228 0.05668483 0.01896288	(8) 1.1890834 0.9563255 0.8545911

the tolerance ellipse is very large for (1), since the outliers severely affected the eigenvalues of the running matrix  $\mathbf{S}^c$ . While the tolerance ellipses are very small for (2), (3), and (4), also due to the outliers severely affected the eigenvalues of the running matrices  $\mathbf{R}^c = \tilde{\mathbf{S}}^c = \tilde{\mathbf{R}}^c$ . The tolerance ellipse is very small for (7) and it does not cover the regular points, due to the first two eigenvalues of (7) are very small. It exemplifies that the results from robust covariance matrix of the scaled data is not very reliable. The tolerance ellipses of (6) and (8) well separate the regular points and the outliers.

### 3.4. Example: Stocks data

In this subsection, we apply the robust factor analysis solution to a real data set `stock611`. This data set consists of 611 observations with 12 variables. The data set is from Chinese stock market in the year 2001. It is used in (Wang 2009) to illustrate factor analysis methods. For `x = stock611[,3:12]`,

```
cov_x = CovRobust(x = x, control = control)
```

gets error message for `control = "mcd", "m", "mve", "sde", "sfast"`, thus we can not compute `cov_x`,  $\mathbf{S}^r$ , and  $\mathbf{R}^r$  for these robust estimators. That is, we can not get results for combinations (5) and (6) for these robust estimators. However, for `x = scale(stock611[,3:12])`, we can compute `cov_x`,  $\tilde{\mathbf{S}}^r$ , and  $\tilde{\mathbf{R}}^r$  for these robust estimators, and we can get results for combinations (7) and (8). Although (6) and (8) have the same running matrices ( $\mathbf{R}$ ), eigenvalues ( $\lambda$ ), loadings ( $\mathbf{L}$ ), uniquenesses ( $\Psi$ ), scoring coefficients ( $\mathbf{S}_c$ ), scaled data matrices (scaledX), and score matrices ( $\mathbf{F}$ ), as were proved in Theorem 3.2, we may not be able to get results for (6) due to computational error for `cov_x`, while for (8) the computational error does not occur. That is why we recommend (4) vs (8) for classical and robust factor analysis. The first two eigenvalues of the running matrices of the `stock611` data of the 8 combinations are given in Table 6. From Table 6 we see that the eigenvalues of (2), (3), and (4) are the same, the eigenvalues of (6) and (8) are the same. The results also illustrate Theorems 3.1 and 3.2.

Classical and robust (OGK) scatterplots of the first two factor scores of the `stock611` data with 97.5% tolerance ellipses are plotted in Figure 8. The scatterplots of the first two factor scores of combinations (1) and (5) are not shown, because errors occur in

```
solve.default(S): system is computationally singular.
```

To get a clearer view of the scatterplots, we zoom in the scatterplots. We see that the scores of (2), (3), and (4) are the same, the scores of (6) and (8) are the same, in agree with Theorem

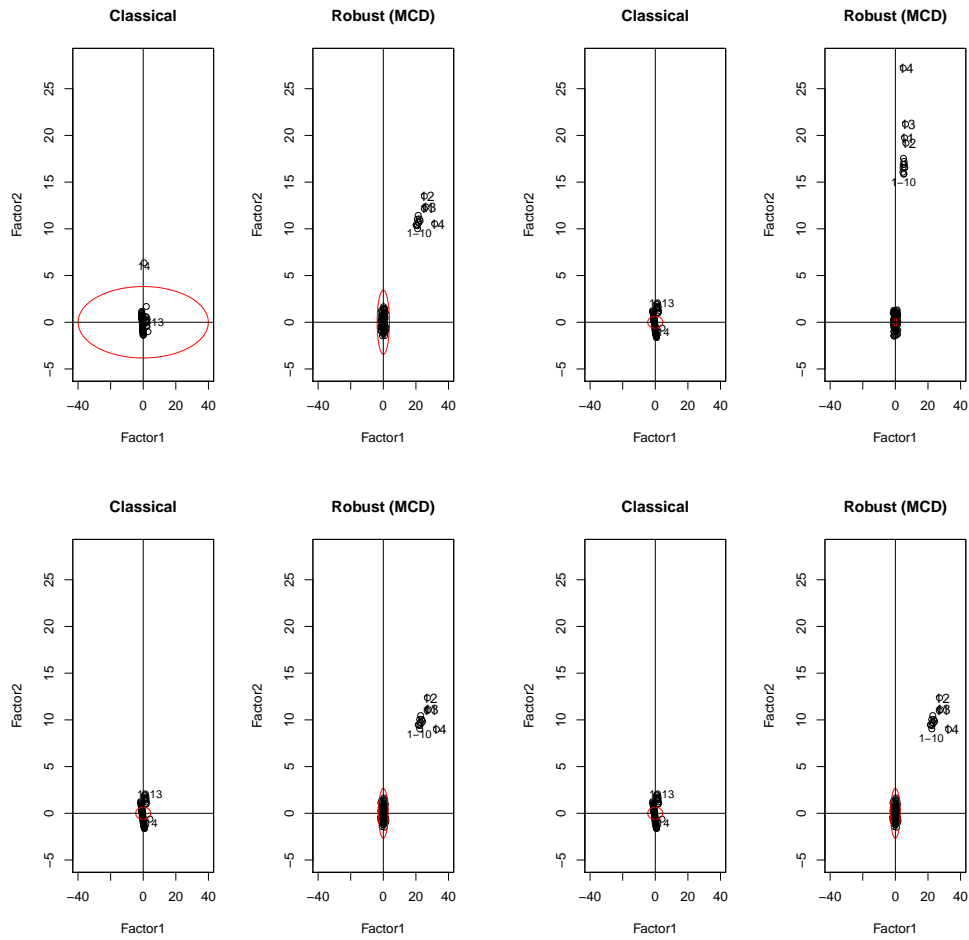

Figure 7: Classical and robust (MCD) scatterplots of the first two factor scores of the hbk data with 97.5% tolerance ellipses. First row: (1) vs (5); (3) vs (7). Second row: (2) vs (6); (4) vs (8).

Table 6: The first two eigenvalues of the running matrices of the stock611 data.

		Classical	Robust (MCD)
stock611[,3:12])	covariance	(1) 4.272384e+20 1.985165e+19	(5) 3.990230e+17 7.358056e+16
	correlation	(2) 5.7900498488 2.3189552681	(6) 5.15840672 2.40502329
scale(stock611[,3:12]))	covariance	(3) 5.7900498488 2.3189552681	(7) 7.527778e-01 2.967432e-01
	correlation	(4) 5.7900498488 2.3189552681	(8) 5.15840672 2.40502329

3.2. Note that the tolerance ellipses for (2), (3), and (4) cover the outliers, due to the outliers severely affected the eigenvalues of the running matrices  $\mathbf{R}^c = \tilde{\mathbf{S}}^c = \tilde{\mathbf{R}}^c$ . The tolerance ellipses of (6) and (8) well separated the regular points and the outliers.

Next we plot a `Cov-class` for the `stock611` data using the function `myplotDD()`. See Figure 9. The figure shows a distance-distance plot. We see that the robust (mahalanobis) distances are far larger than the (classical) mahalanobis distances. The outliers have large robust distances.

```
cutoff = 4.525834
```

```
id.n <- length(which(rd>cutoff))
```

```
id.n = 287
```

Here `y` is the robust distance (`rd`).

```
sort.y = (To save space, only the smallest five and largest five
elements of sort.y$x and sort.y$ix are shown.)
```

```
$x
```

```

Figure 8: Classical and robust (OGK) scatterplots of the first two factor scores of the stock611 data with 97.5% tolerance ellipses. First row: (2) vs (6). Second row: (3) vs (7). Third row: (4) vs (8).

Figure 9: A distance-distance plot for stock611 data.

From the above results we see that the `cutoff` is computed as 4.525834. There are `id.n = 287` observations with robust distances larger than `cutoff`. `sort.y` is a list containing the sorted values of `y` (the robust distance). `sort.y$x` is arranged in increasing order. To save space, only the smallest five and largest five robust distances with their indices are shown. `sort.y$ix` contains the indices. `ind` shows the indices of the largest `id.n = 287` observations whose robust distances are larger than `cutoff`.

From the above results, we recommend (4) vs (8) when one needs to compare classical and robust factor analysis. The following code lines generate an object `faClassic4` of class `FaClassic`.

```
R> ## (4) classical, x = scale(stock611[,3:12]), cor = TRUE (correlation matrix)
R> faClassic4 = FaClassic(x = scale(stock611[,3:12]), factors = 2, cor = TRUE,
+ method = "pca", scoresMethod = "regression"); faClassic4
```

Call:

```
FaClassic(x = scale(stock611[, 3:12]), factors = 2, cor = TRUE,
method = "pca", scoresMethod = "regression")
```

Standard deviations:

```
[1] 2.40625224 1.52281163 1.00433419 0.75771973 0.37846924 0.31490830
[7] 0.22719326 0.09697058 0.06300416 0.02779799
```

Loadings:

	Factor1	Factor2
X1	0.98781949	-0.02611587
X2	0.99154548	-0.00633362

X8  0.04578987  0.88138600
X9  0.94053884 -0.01792872
X10 0.99068004 -0.04474676

```

```
R> summary(faClassic4)
```

Call:

```
FaClassic(x = scale(stock611[, 3:12]), factors = 2, cor = TRUE,
          method = "pca", scoresMethod = "regression")
```

Importance of components:

	Factor1	Factor2
SS loadings	5.785	2.324
Proportion Var	0.579	0.232
Cumulative Var	0.579	0.811

Since we use the correlation matrix (`cor = TRUE`) as the running matrix, the entries of the loading matrix are limited between 0 and 1, which makes the explanations of the factors easy. From the `show` result of `faClassic4`, we see that its `Factor1` explains variables `x1-x4`, `x9`, `x10`; its `Factor2` explains variables `x5-x8` (with loadings larger than 0.48). From the `summary` result of `faClassic4`, we see that the first two factors account for about 81.1% of its total variance.

Next we generate an object `faCov8` of class `FaCov` using the same data set.

```

R> ## (8) robust, x = scale(stock611[,3:12]), cor = TRUE (correlation matrix)
R> faCov8 = FaCov(x = scale(stock611[,3:12]), factors = 2, cor = TRUE, method = "pca",
+ scoresMethod = "regression", cov.control = CovControl0gk()); faCov8

```

Call:

```
FaCov(x = scale(stock611[, 3:12]), factors = 2, cor = TRUE, cov.control = CovControl0gk(),
      method = "pca", scoresMethod = "regression")
```

Standard deviations:

```

[1] 2.2712126 1.5508138 1.0753673 0.8269330 0.4632001 0.4302182
[7] 0.3448025 0.1828619 0.1768218 0.1144628

```

Loadings:

	Factor1	Factor2
X1	0.1192720	0.771765320
X2	0.3585258	0.808017502
X3	0.7582825	0.596037255
X4	0.7604049	0.586322722
X5	0.9546105	0.072062014
X6	0.4300313	0.111234443

```

X7  0.8787653 -0.002537877
X8  0.9349237 -0.028219013
X9  0.0457114  0.931164519
X10 -0.0712708  0.827516094

```

```
R> summary(faCov8)
```

Call:

```
FaCov(x = scale(stock611[, 3:12]), factors = 2, cor = TRUE, cov.control = CovControlOgk(),
      method = "pca", scoresMethod = "regression")
```

Importance of components:

	Factor1	Factor2
SS loadings	4.046	3.518
Proportion Var	0.405	0.352
Cumulative Var	0.405	0.756

From the `show` result of `faCov8`, we see that its `Factor1` explains variables `x3-x8` (with loadings larger than 0.43); its `Factor2` explains variables `x1-x4`, `x9`, `x10`. Thus `Factor1` (`Factor2`) of `faClassic4` and `Factor2` (`Factor1`) of `faCov8` are similar. In fact, this is not the general case. That is, in most of the situations, the explanations of the factors of `faClassic4` and `faCov8` should be the same. From the `summary` result of `faCov8`, we see that the first two factors account for about 75.6% of its total variance.

The classical and robust scatterplots of the first two factor scores of the `stock611` data are shown in Figure 10. From the figure we see that `Factor1` (`Factor2`) of `faClassic4` and `Factor2` (`Factor1`) of `faCov8` are similar in patterns.

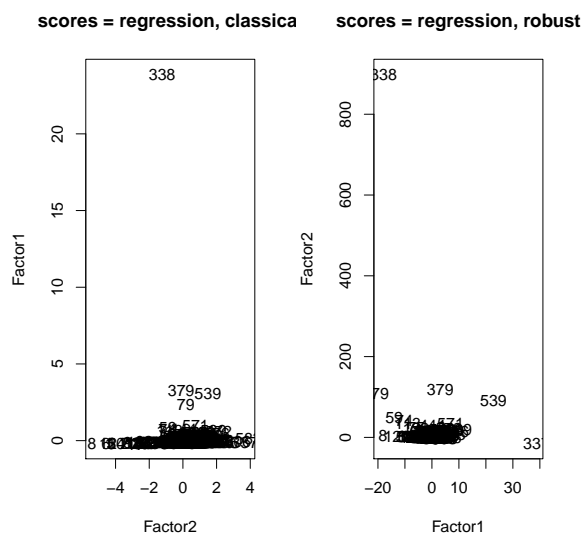

Figure 10: Classical and robust scatterplots of the first two factor scores of the `stock611` data.

Furthermore, by inspecting the classical and robust ordered scores, we find that they are quite different. In the following, `orderedFsC[[1]]` and `orderedFsOgk[[1]]` are decreasing

according to their first column; `orderedFsC[[2]]` and `orderedFsOgk[[2]]` are decreasing according to their second column.

```
R> orderedFsC = fsOrder(faClassic4@scores[,2:1]); orderedFsC
```

```
R> Lst=list(orderedFsC[[1]][1:10,], orderedFsC[[2]][1:10,]); Lst

## 4. Conclusions

We presented an object-oriented solution for robust factor analysis developed in the S4 class system of the programming environment R. In the solution, new S4 classes "Fa", "FaClassic", "FaRobust", "FaCov", "SummaryFa" are created. The classical factor analysis function `FaClassic()` and the robust factor analysis function `FaCov()` both can deal with maximum likelihood estimation, principal component analysis, and principal factor analysis methods. Consider the factor analysis methods (classical or robust), the data input (data or the scaled data), and the running matrix (covariance or correlation) all together, there are 8 combinations. We recommend (4) (classical factor analysis using the correlation matrix of the scaled data as the running matrix) vs (8) (robust factor analysis using the correlation matrix of the scaled data as the running matrix) for theoretical and computational reasons. The application of the solution to multivariate data analysis is demonstrated on the `hbk` data and the `stock611` data which themselves are parts of the package `robustfa`. A major design goal of the object-oriented solution was the openness to extensions by the development of new robust factor analysis methods in the package `robustfa` or in other packages depending on `robustfa`.
